The experiments have confirmed the conclusions of others that about one-tenth of the bacterial content of milk immediately after being drawn is derived from the interior of the udder. The species of bacteria were found to vary in different cows, but were always constant for the same cow. *Bacterium güntheri* liquefactive in the milk of two cows, white liquefying micrococci for the milk of the third cow, and liquefying micrococci and streptococci in the milk of the fourth were the species found.

The fermentation test applied to these samples showed that the liquefying *B. güntheri* is the chief factor exerting an unfavorable influence on the phenomena of lactic fermentation. This organism causes the formation of a curd whose degree of consistency is intermediate between that of casein and that of whey-curd.

These results show that the bacteria of the udder may have injurious effects on the quality of milk and its derivatives.

A common, but incorrect, statement concerning the number of bacteria in milk, R. S. BREED (*Science*, n. ser., 44 (1916), No. 1143, pp. 749, 750).—The author advocates the abandonment of the present custom of referring to agar-plate counts as showing the number of bacteria in milk, since these counts show only the number of colonies developing on the nutrient medium under the conditions of incubation used. Studies at the New York Cornell and Geneva experiment stations are cited which tend to show that the actual number of bacteria in milk may be from 2 to 25 times the number of colonies developing on agar plates even after prolonged incubation.

Cheese factory and creamery instruction and inspection (*Agr. Gaz. Canada*, 3 (1916), No. 11, pp. 964-985, figs. 8).—This is a series of articles in which there

are brought together the policies and methods of the different Provinces of Canada with reference to cheese factory and creamery instruction and inspection.

The chromogenic micro-organisms of cheese and their presence in the Italian "robbiola," G. DALLA TORRE (*Staz. Sper. Agr. Ital.*, 49 (1916), No. 1, pp. 59-67; *abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 4, p. 600).—The author gives a list of the principal chromogenic micro-organisms occurring in cheese, with notes on their action and the results of a bacteriological analysis of a sample of robbiola cheese made for the purpose of determining the micro-organisms causing the spongy interior and yellow outside cover of this cheese.

The sponginess was found to be due to a bacterium of the *B. aerogenes-coli* group. Of the 13,000,000 bacteria per gram of cheese, 200,000 belonged to this group. The remainder were chiefly *B. lactis acidi*. The micro-organism causing the yellow exterior coloration in robbiola cheese was found to be a distinct species with the following characters: Micrococcus, 0.8 to 1  $\mu$  in diameter; produces a yellow or yellowish green substance; necessarily aerobic; coagulates milk and dissolves the coagulate, giving an acid reaction; and loses its coloring properties and odor when cultivated several times in succession.

The preparation of homemade rennet, A. TODD and ELFRIDA C. V. CORNISH (*Jour. Bd. Agr. [London]*, 23 (1916), No. 5, pp. 459-462, fig. 1; *Bd. Agr. and Fisheries [London], Leaflet 60* (1916), pp. 4, fig. 1).—Detailed directions are given for the preparation of rennet from the fourth stomach of calves. It is stated that rennet prepared by the method described has been used in cheese making with apparently satisfactory results.

## VETERINARY MEDICINE.

The pathology and differential diagnosis of infectious diseases of animals, V. A. MOORE (*New York: The Macmillan Co., 1916, 4. ed., rev. and enl., pp. XVI+593, pl. 1, figs. 120*).—A revised and enlarged edition of the work previously noted (*E. S. R.*, 21, p. 579). Two appendixes have been added, one on the requirements for interstate shipment of live stock and the other on the Federal regulations for the veterinary inspection of meat.

Special pathology and therapeutics of the diseases of domestic animals, F. HUYRA and J. MAREK, edited by J. R. MOHLER and A. EICHHORN (*Chicago: Alexander Eger, 1916, 2. ed., vols. 1, pp. XVI+1213, pls. 12, figs. 231; 2, pp. XVII+1108, pls. 7, figs. 207*).—This second English edition of the work previously noted (*E. S. R.*, 28, p. 778), based on the fourth revised and enlarged German edition, contains much information gained since the publication of the third edition. It includes the new features of the fourth German edition, and in many instances the editors have added other data relating especially to conditions prevalent in this country.

The first volume, in addition to new chapters on paratyphus of hogs and on sporotrichosis, also contains many elaborations in most of the chapters, especially with reference to etiology, allergic reactions, serodiagnostic methods, and immunizations. Ascoli's precipitation reaction in anthrax and swine erysipelas and the salvarsan treatment in contagious pneumonia of horses have been given due consideration. The chapter on protozoan diseases has been carefully revised and brought up to date. The authors have felt justified in separating and differentiating the catarrhal form of influenza from the pectoral form or contagious pneumonia of horses.

In the second volume, on organic diseases, new chapters have been prepared on catarrh of the sphenoidal sinus, dysentery, localization of the cerebral affec-

tions, infantile paralysis, guinea pig paralysis, paralysis of the hypoglossal nerve, tetany, necrobacillary ostitis and osteomyelitis, etc. Infectious spinal meningitis of horses (Borna disease) has been revised and separated from the other forms of meningo-encephalomyelitis (meningitis cerebrospinalis enzootica). The chapters on progressive pernicious anemia, leukemia of mammals, pseudoleukemia, blood filaria, nephritis, catarrh of the guttural pouches, pharyngitis, traumatic gastritis, intestinal hemorrhage, gastro-enteritis, cerebral diseases, affections of the peripheral nerves, neuroses, serum disease, pemphigus, and parasitic affections of the organs have been either entirely revised or markedly changed. A uniform arrangement has been followed in practically every fever chart, and references to recent literature have been included.

**Text-book of special pathology and therapy of domestic animals**, E. FRÖHNER and W. ZWICK (*Lehrbuch der speziellen Pathologie und Therapie der Haustiere*. Stuttgart: Ferdinand Enke, 1915, 8. rev. ed., vol. 1, pp. XVI+929, figs. 89).—This is the eighth revised edition of the work previously noted (E. S. R., 12, p. 596). This volume deals with the diseases of the digestive organs, liver, abdomen, kidneys, reproductive organs, heart and blood vessels, skin, organs of locomotion, nervous system, and organs of respiration, and chronic constitutional diseases. A classified bibliography of the literature relating to these diseases is appended (pp. 829-916).

**The origin and development of the lymphatic system**, FLORENCE R. SABIN (*Johns Hopkins Hosp. Rpts.*, 17 (1916), pp. 347-440, figs. 19).—As is pointed out by the author the fundamental morphology of the lymphatic system has been established, but there remain many gaps in our knowledge of the system as a whole.

**Relationship between serum reactions**, H. WEHREIN (*Jour. Infect. Diseases*, 19 (1916), No. 6, pp. 806-810).—From a study of the relation of the numerical values of the titers of serum reactions the author found that there was no coincidence between the titers of hemagglutinins and hemolysins, either against the same antigen or against different antigens. Using *Bacillus coli*, *B. subtilis*, and *B. pyocyaneus*, no relation between the agglutinin titers was observed. A rather even production of seroprecipitins, however, was obtained in three tests of five rabbits each, horse, pig, and sheep serum being used as antigen.

**Relation of specific precipitation to other immunity reactions**, H. A. BULGER (*Jour. Infect. Diseases*, 19 (1916), No. 6, pp. 832-839).—Experiments are reported from which it is concluded that "in small amounts the precipitate formed by action of immune serum and antigen, and also sensitized organisms, will remove antiferments from sera. This may show the relation of precipitins to anaphylactic and Abderhalden reactions. The absorbing action of sensitized organisms and precipitate is not specific. They will remove the antiferment not only from the homologous sera but also from heterologous sera. There is a quantitative relation between the amounts of precipitate and sensitized organisms and the maximal amount of absorption of the antiferment."

**Hypodermal anaphylaxis**, F. TORRANCE (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 3, pp. 309-311, figs. 2).—Experiments by S. Hadwen, of the Health of Animals Branch of the Department of Agriculture, Canada, are noted in which cattle were inoculated with an extract of *Hypoderma boris*. Shortly after the inoculation the animals began to salivate, tears ran from the eyes, gaseous feces and clear mucus were passed, there was rapid breathing, labored heart action, and a purplish coloration of the skin. Very soon the lids became swollen and the anus became edematous.

An animal injected with an extract of eight *H. lineatum* larvæ developed the symptoms before the inoculation was completed and died within five minutes.

It is indicated that cattle harboring warble larvæ become sensitized to them, and that when the system becomes suddenly flooded with the protein of the larvæ (and possibly toxins) anaphylactic shock results.

The effect of toluene on the production of antibodies, L. HEKTOEN (*Jour. Infect. Discases*, 19 (1916), No. 6, pp. 737-745).—Similar experiments to those made with benzene, previously noted (E. S. R., 35, p. 781), were made with toluene, and the results reported.

In repeated doses of about 1 cc. per kilogram of body weight the toluene diminished the output of antibody in the earlier periods of antibody production, and under certain conditions caused long persistence of antibody in the blood, with marked fluctuations in the concentration in some of the cases. The same increased persistence of antibody in the blood may result from the injection of smaller doses of toluene.

No immediate change as to number and proportion of leucocytes in the blood of rabbits nor any change in the phagocytic activity of the leucocytes in vitro was observed.

"In rabbits receiving the larger doses of toluene there occurs a transitory myeloid hyperplasia in the bone marrow, but later no marked changes in the marrow or other organs appear. On this account there is at present no basis for concluding whether the fluctuation and persistence of antibodies in the blood is better explained as resulting from increased and prolonged production of antibodies, or as resulting from interferences with the passage of antibodies out of the blood."

Comparative action of antiseptics on pus and on pure cultures, A. LUMIÈRE (*Compt. Rend. Acad. Sci. [Paris]*, 163 (1916), No. 13, pp. 309-311).—Data are submitted which show the marked effect of the albuminous material of pus in decreasing the bactericidal action of phenol, hermophenyl (mercuric phenol disodium sulphonate), and sodium hypochlorite.

For the treatment of suppurating wounds the free use of relatively concentrated hypochlorite solutions is recommended. It is indicated that the hypochlorite oxidizes the toxins of the pus and plays an important part in the defense of the organism against intoxication and the spread of infection.

The significance of certain natural flagellates of insects in the evolution of disease in vertebrates, H. B. FANTHAM and ANNIE PORTER (*Jour. Parasitology*, 2 (1916), No. 4, pp. 149-166, figs. 2).—A further report of work (E. S. R., 35, p. 782).

Observations on the blood in East Coast fever of cattle, C. STRICKLAND (*Parasitology*, 8 (1916), No. 3, pp. 244-248).—"There is very little, if any, abnormal destruction of erythrocytes in cases of infection with East Coast fever. This is proved by blood counts, hemoglobin estimations, and the condition of the blood-forming and blood-destroying organs, all remaining practically normal. This is in marked contrast to what obtains in piroplasmosis.

"The hypothesis advanced by Nuttall fits all the facts. According to this hypothesis the invasion of the corpuscles occurs in the internal organs where the parasites develop, and the corpuscles only act as carriers of the parasites in the blood, thereby conveying them to the tick which serves as the vector. Since few, if any, of the corpuscles are destroyed they rapidly become charged with an increasing number of parasites, which are being continuously produced in the internal organs as evidenced by Koch's blue bodies which form and break up in the lymphatic glands, spleen, liver, bone marrow, etc. (Gonder, Nuttall).

"There is a marked leucopenia in East Coast fever, the polymorphs decreasing less rapidly than the other elements. This is in contrast with the leucocytosis observable in piroplasmosis."

The significance of the mallein ophthalmic test as a diagnostic aid in the control of glanders, J. BONGERT (*Monatsh. Prakt. Tierheilk.*, 27 (1916), No. 5-6, pp. 177-233, figs. 2).—From the results of a thorough study the author concludes that the ophthalmic mallein test is as trustworthy as the serological test and is much simpler and easier to manipulate, especially in the diagnosis of a large number of animals. For the practical diagnosis of glanders the combined ophthalmic and serological test is recommended. This procedure is deemed the safest and most rapid to use in order to prevent the unnecessary killing of healthy animals.

The importance of repeated biological tests in the control of a glanders epizootic is emphasized. In a first examination of an animal the combined test indicated above should always be used. In view of the fact that in a recurrence of the disease both the ophthalmic and serological tests may yield negative results, a thorough clinical examination at no time should be neglected. Without such examination it is deemed impossible to control or eradicate an epizootic.

The presence of tetanus bacilli on the surface of parts of projectiles left in healed wounds, A. LUMIÈRE (*Compt. Rend. Acad. Sci. [Paris]*, 163 (1916), No. 15, pp. 378-380).—A number of cases are reported in which symptoms of tetanus developed after the healing of the wound. It is considered that the pieces of projectiles left in the healed wounds carried spores of tetanus bacilli which developed and caused a reinfection. It is indicated that in such cases proper precautions should be taken and the extraneous material removed if possible. Antitetanic serum should also be reinjected at the time of the second operation.

A contribution to the value of the avian tuberculin test of Van Es and Schalk, H. SCHORNAGEL (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 17 (1915), No. 3-4, pp. 170-176, fig. 1).—Experimental data obtained by the use of the intracutaneous tuberculin test of Van Es and Schalk (*E. S. R.*, 31, p. 582) are submitted. The author concludes that the procedure is a valuable diagnostic aid in the detection of avian tuberculosis, and that its manipulation is both simple and rapid.

The economic importance of detecting and eradicating the disease in a flock is emphasized.

The intracutaneous tuberculin test of Van Es and Schalk as a diagnostic aid in avian tuberculosis, H. JAKOB and L. GAZENBEEK (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 17 (1915), No. 3-4, pp. 177-191, figs. 6).—The authors tested 24 birds by the method of Van Es and Schalk (*E. S. R.*, 31, p. 582), of which 16 were tubercular. The remaining fowls were nontubercular and gave negative reactions. Of the 16 cases 8 yielded positive, 2 doubtful, and 6 negative reactions.

The use of the method is deemed to be an important step in the early diagnosis of the disease. A bibliography of 21 references to the literature cited is appended.

A study of the milk in bovine infectious abortion, W. GILTNER, L. H. COOLIDGE, and I. F. HUDDLESON (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 2, pp. 157-167).—Experiments carried out to determine whether *Bacillus abortus* antibodies could be made to appear in the sera of adults by ingestion of infected milk are reported.

Of the seven adults drinking such milk five developed a slight increase in the antibody content of the blood, but in no case was there a marked increase. In only one case did the reaction persist after four weeks from the last drinking of the infected milk. Another experiment, conducted to throw some light on the pathogenic or antigenic properties of *B. abortus* in milk on humans, showed that there was no appreciable increase of the antibody content in the

blood of the individuals and no untoward effects observable. In this experiment negative milk to which 10 cc. of a 48-hour culture of *B. abortus* was added was consumed in quantities of 1 pint per day for a period of six weeks. "There seems to be little evidence to warrant a statement that *B. abortus* in milk is either pathogenic or antigenic to any marked degree for the human adult at least."

Further experiments were conducted in which guinea pigs were fed on naturally infected milk and the results were again negative. "We feel, therefore, that there is not sufficient evidence to condemn positive milk as dangerous to guinea pigs by ingestion, since it has shown no pathogenic action and only slight antigenic action."

Pregnant and nonpregnant rabbits were fed with naturally infected milk for a period of 124 days, the serological results being negative, and no lesions being found in the animals on autopsy. In another series six animals were fed noninfected milk plus a culture of *B. abortus* daily. Two litters of young were born to each rabbit during the experiment, but no abortions occurred in any of the animals, nor were any lesions found on autopsy. It is concluded that positive milk is not dangerous to rabbits by ingestion, since no pathogenic action and only a very slight antigenic action results therefrom.

Calves were fed with naturally infected and noninfected milk at the rate of 1 gal. of milk twice daily to each calf for a period varying from five to 14 weeks. From the results obtained it is concluded that "there is no connection whatever between the feeding of infected or noninfected milk and the matting and staining of the sexual hairs of newborn calves. That *B. abortus* antibodies develop in calves as a result of ingesting naturally infected milk seems to us to be a demonstrated fact, but the cause and significance of the appearance of the antibodies can not be explained until further development of the studies on the calves. The antibodies may be due to an active infection, they may be due to an active immunity, or they may be due to a passive transmission of the antibodies present in the milk. The possibility of infections being acquired in utero seems to us to be a phase of the abortion question that should be given as much attention as other possible modes of infection. Since we have found that 16 per cent of the 12 calves used in this experiment possessed *B. abortus* antibodies at the time of birth, and that the antibodies persisted for many weeks after birth, we conclude that the control of the disease must begin with a study of the calf at the time of birth." The experiments are described in detail.

A further experiment is reported which shows that milk containing *B. abortus* antibodies is highly bactericidal toward the organism. "Therefore milk containing *B. abortus* antibodies that has been heated at a sufficient temperature to kill the organisms and not the antibodies should be looked upon as being beneficial to newborn calves. The milk containing antibodies should give the calf a passive immunity during its early development."

**The significance and duration of immunity in bovine contagious abortion.** A. ASCOLI (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 17 (1915), No. 3-4, pp. 156-169).—The results of experiments in which guinea pigs were inoculated with *Bacillus abortus* which had been killed with ether, followed by the inoculation of living cultures, are reported. After various periods of time the animals were killed and the spleen examined bacteriologically for the microorganism.

The results showed that immunization in guinea pigs with killed microorganisms does not bring about an increase in resistance to the virus. The animals so inoculated appeared to be even more susceptible to infection than

normal animals. The use of larger doses of the killed organisms caused no difference as to the susceptibility.

Experiments with rats are also described and discussed.

The seasonal prevalence of *Hypoderma bovis* in 1915, together with observations on the terrifying effect *H. bovis* has upon cattle and lesions produced by the larva, S. HADWEN (*Ann. Rpt. Ent. Soc. Ontario, 46 (1915), pp. 108-119, figs. 4*).—"The seasonal activity of *H. bovis* at Agassiz is from the beginning of June to the beginning of August. The last larvæ to emerge from the backs of cattle leave during the first days of July. In *H. bovis* the pupal period averages 35 days. High temperatures shorten the pupal period. The fear cattle have for *H. bovis* is due to the insect's persistence and manner of egg laying. Hewitt's observations on the penetration of the skin by the larvæ of *H. bovis* are confirmed. The lesions caused by the larvæ differ from those of *H. lineatum*. Older animals show more lesions than the young."

Castration of young pigs, F. G. ASHBROOK (*U. S. Dept. Agr., Farmers' Bul. 780 (1916), pp. 6, figs. 6*).—A descriptive account prepared for the farmer.

Hog cholera (*North Dakota Sta. Rpt. 1916, pp. 13-15*).—Immunization experiments with a virus from normally susceptible pigs infected by exposure or injection, from serum-infected pigs which sickened in the course of a serum test, from pigs injected with blood from a hyperimmune hog immediately after hyperimmunization, and from hogs which escaped infection after injection with blood from a hyperimmune hog but became infected by injection of virus from normally susceptible pigs infected by exposure or injection are noted. The results indicate that "at least the antigenic properties of a virus may be seriously affected by the protective factors with which it may come in contact during passage."

Experiments to determine the relative resistance of antibodies in antihog-cholera serum to various adverse influences showed that serum kept in a refrigerator for a period of six years retained its full potency at the end of the period. Serum kept at room temperature (70° F.) for a period of 212 days protected an 89-lb. pig by a dose of 35.6 cc., and a 74-lb. pig by a dose of 14.8 cc. "Serum kept at a body temperature for a period of 212 days protected a 74-lb. pig by a dose of 29.6 cc., but failed to protect a 71-lb. pig by a dose of 14.22 cc." Serum kept in a practically permanent frozen condition for over three months was still able to protect pigs.

It is indicated, however, that these results do not render the usual precautions observed in storing and keeping serum unnecessary.

Meeting of committee appointed to recommend best methods of vaccination, control, and eradication of hog cholera (*Indiana Sta. Circ. 56 (1916), pp. 20*).—This circular reports in detail the proceedings at a meeting held March 10, 1916, of a committee appointed at the Fourth Annual Hog Cholera Conference.

The committee, in resolutions adopted, recommended "a more extensive educational campaign among veterinarians and stockmen along sanitation and vaccination lines; the reporting of outbreaks of hog cholera and all herds that are vaccinated to the state veterinarian; the placarding of premises infected with hog cholera; the licensing of persons using hog-cholera blood for vaccinating hogs; . . . the use of hog-cholera blood in doses not less than 1 cc. for the simultaneous vaccination of hogs, and antihog-cholera serum in not less than 20 cc. doses for small pigs, and 30 cc. for pigs weighing 100 lbs., or preferably 40 cc. when used simultaneously; and . . . that the state veterinarian be given the necessary control over the distribution of hog-cholera virus and serum, enabling him to condemn and confiscate any antihog-cholera serum or hog-cholera blood that is impotent, contaminated, or dangerous, in order that he may better

protect the interests of stockmen against losses following vaccination." The indiscriminate use of the simultaneous method of vaccination in nonexposed herds was pointed out as a source of danger, and was not recommended.

*Bacillus abortus* as an etiological factor in infectious abortion in swine, E. S. GOOD and W. V. SMITH (*Jour. Bact.*, 1 (1916), No. 4, pp. 415-422).—The authors at the Kentucky Experiment Station isolated *B. abortus* from the afterbirth of an aborting sow and from the contents of the umbilicus, heart, liver, and stomach of two aborted fetuses. The strain isolated from the sow responded to all the biological and physiological tests of the strains isolated from the uterine exudates of aborting cows, except that the original culture grew in the air after the first generation.

The intravenous inoculation of a pregnant sow with 2 cc. of an agar slant culture in normal saline of the bacillus secured from the aborting sow caused an abortion in 17 days. Feeding the organism to another pregnant sow produced an abortion in 19 days. The organism was again isolated from the aborted fetuses. "The blood serum of each of these sows, after aborting, completely agglutinated a strain of *B. abortus* derived from an aborting cow, in a dilution of 1:100. The complement was fixed in each case with 0.02 cc. of the serum. The serum of a normal hog did not agglutinate in any dilution, nor did it fix the complement."

Equine spirillosis in Morocco, VELU (*Rec. Méd. Vét.*, 92 (1916), No. 7, pp. 215-224, figs. 2).—The author reports the occurrence of an equine spirillosis in Morocco which may be confounded clinically with cases of trypanosomiasis. The affection is benign and experimental diagnosis is easy, since the causal agent is inoculable into the dog, rabbit, and white rat.

Leukemia of the fowl: Spontaneous and experimental, H. C. SCHMEISSER (*Johns Hopkins Hosp. Rpts.*, 17 (1916), pp. 551-586, pls. 4).—"The spontaneous occurrence of myeloid leukemia of the fowl is confirmed. Myeloid leukemia in the fowl is transmissible by the intravenous or intraperitoneal injection of an organic emulsion."

The rôle of the flagellated protozoa in infective processes of the intestines and liver, P. B. HADLEY (*Rhode Island Sta. Bul.* 166 (1916), pp. 3-40, pls. 3).—In this contribution the author presents evidence of the pathogenic rôle of the flagellated protozoan, *Trichomonas*, in an almost invariably fatal cecal and hepatic infection in birds. In the first part he deals with the infecting organism and in the second with the parasites in the tissues.

The *Trichomonas* studied is found in the intestines of all poultry, as well as of most other animals. In the intestines the flagellates are present in the cecal contents, but are found mainly in the mucus layer overlying the epithelium, and often deep in the crypts of Lieberkühn. Reproduction is by simple fission, taking place mainly in the cecal content; also by encystation and spore formation, probably the common method of reproduction in the tissues. Ameboid forms are also encountered, especially in the tissues.

"The gross pathological picture includes congestion and enlargement of portions of the whole or part of one or both ceca, together with the presence of large, circular, yellowish, discrete or confluent, necrotic areas on the liver. These foci extend deep into the tissues. Frequently the ceca may contain a solid, cheesy or leathery, yellow or blood-stained core, composed of coagulated serum, fibrin, and cellular elements. The lumina are frequently quite obliterated. Fusions between the ceca and loops of the intestine, liver, or gizzard may sometimes occur; also between the liver and proventriculus.

"The microscopical pathological features involve the penetration of the epithelial wall by the parasites and a progressive infection of the subepithelial

tissues, where the mode of reproduction is by encystation and spore formation. The result of rapid reproduction is great thickening of the cecal wall. In favorable specimens many of the features of flagellate morphology can be observed in the parasites located in these regions. The liver presents a corresponding appearance of the infecting elements, though more modified by their location.

"Very rarely the pathological condition may be complicated in the liver by an amebic infection (not *Amœba melcagridis*) and in the ceca by both amebas and coccidia (*Eimeria avium*). The picture may also be complicated by infections with Hemoproteus.

"The nature of the infective process, together with extensive clinical experience, makes it clear that intestinal flagellatosis can not be regarded as an infectious disease, and that *Trichomonas* as found in these infections can not be looked upon as a pure parasite. A successful infection depends upon factors present in the host, and is probably quite unrelated to 'virulence' on the part of the infecting organism. In this sense the infection, commonly called 'black-head' of turkeys, can not be regarded as an infectious or communicable disease.

"The parasitic flagellates here described are identical with some of the bodies earlier regarded by the writer as stages in the development of the coccidium, *Eimeria*. They are also identical with bodies described by Theobald Smith under the name *A. melcagridis*, of whose existence, as an ameba, up to the present time no conclusive evidence has been brought forward."

## RURAL ENGINEERING.

The people's interest in water-power resources, G. O. SMITH (*U. S. Geol. Survey, Water-Supply Paper 400-A (1916), pp. 8*).—This is an address delivered before the Second Pan-American Scientific Congress at Washington, December 28, 1915.

Accuracy of stream-flow data, N. C. GROVER and J. C. HOYT (*U. S. Geol. Survey, Water-Supply Paper 400-D (1916), pp. 53-59*).—It is pointed out in this report that "notes on accuracy that accompany stream-flow records should give, first, information by which the technical man may study the records and judge their accuracy, and second, information by which both the general and the technical user may judge the reliability of the records without making a study." The conditions affecting the accuracy of records of daily discharge are discussed as "permanence of the stage-discharge relation, precision with which the discharge rating curve is defined, refinement of gage readings, frequency of gage readings, [and] methods of applying the daily gage heights to the rating table to obtain the daily discharge."

The measurement of silt-laden streams, R. C. PIERCE (*U. S. Geol. Survey, Water-Supply Paper 400-C (1916), pp. 39-51, figs. 2*).—An account of the special difficulties encountered and the results obtained in measuring the flow of the San Juan River are given.

Surface water supply of the Pacific slope basins in California, 1913 (*U. S. Geol. Survey, Water-Supply Paper 361 (1916), pp. 514, pls. 2, fig. 1*).—This report, prepared in cooperation with the State of California, presents the results of measurements of flow made on streams in the Pacific slope drainage basins in California during 1913.

Surface waters of Massachusetts, C. H. PIERCE and H. J. DEAN (*U. S. Geol. Survey, Water-Supply Paper 415 (1916), pp. 433, pls. 12, figs. 6*).—This report describes the general features and gives the results of measurements of flow made on streams in the Housatonic, Connecticut, Taunton, Charles, and Merri-

mac river basins in Massachusetts. A gazetteer of the streams of the State is appended.

Ground water in southeastern Nevada, E. CARPENTER (*U. S. Geol. Survey, Water-Supply Paper 365 (1915), pp. 86, pls. 5, figs. 3*).—This report deals with the geography, geology, and climate, and the occurrence, amount, distribution, and quality of the ground water of an area of about 17,000 square miles in southeastern Nevada, the topographic features of which consist "of a series of parallel north-south mountain ranges and intervening broad debris-filled valleys." Analyses of 42 samples of the water showed that for domestic use 24 were good, 6 were fair, 8 were poor, 3 were bad, and 1 was unfit. For irrigation use 31 were good, 5 were fair, and 6 were poor.

The Navajo country: A geographic and hydrographic reconnaissance of parts of Arizona, New Mexico, and Utah, H. E. GREGORY (*U. S. Geol. Survey, Water-Supply Paper 380 (1916), pp. 219, pls. 29, figs. 29*).—This report deals with the geography, climate, and surface and ground waters of the Navajo and Hopi Indian reservations in Arizona, New Mexico, and Utah, covering an area of about 14,333,354 acres.

"Bare rock constitutes a large proportion of the surface of the Navajo Reservation outside the larger washes. . . . As a whole the soil is, however, mainly accumulated in the washes and along the smaller stream channels, where deposits exceeding 50 ft. in depth are not unusual." These alluvial deposits have a composition almost wholly of sand and gravels.

"By methods of flood irrigation the Navajo and Hopi together cultivate about 20,000 acres of land widely distributed over the reservation in fields about 3 acres in average size, rarely exceeding 200 acres. Considering the size of fields, the nature of the soil, the fluctuating flow of streams, and the large amount of debris carried in the flooded channels, this method of control by inexpensive dams, rebuilt each season, is satisfactory, but the amount of water lost is enormous." With reference to irrigation by storage, it was found that "the storage grounds along the perennial streams of the Chuska Mountains and of the Carrizo and Navajo mountains are at altitudes which prohibit the cultivation of crops other than those which survive large ranges in daily temperature and can endure frost at any month in the year. Water from reservoirs thus located must be carried 10 to 30 miles before it can reach large tracts suitable for general agriculture. In general the largest tracts of irrigable land are farthest from permanent streams. The deeper canyons—Navajo, Piute, Laguna, upper Moenkopi, Del Muerto, and others now occupied by streams—contain little arable land. The construction of dams for storage of flood water in the wide alluvium-filled washes presents engineering difficulties surmountable only at prohibitive cost, a statement amply supported by a formidable catalogue of failures. The amount of silt carried along the large valleys is sufficient to cause embarrassment. . . .

"The alluvial filling of washes and canyons is, in general, fine and coarse sand rather than silt and clay; the soil absorption and underground flow is correspondingly large." "Tests were made of flood water taken from the larger washes and allowed to settle from 12 to 36 hours. Eight such tests gave an apparent percentage of sediment ranging from 6 to 25. One record of 34 per cent was obtained, and a sample taken from a tributary of the Little Colorado was found after 16 hours to have deposited nearly half its bulk."

Special sections on domestic and stock water supplies are also included. An extensive bibliography on the region is appended.

Harney and Silver Creek projects, irrigation and drainage, J. T. WHISTLER and J. H. LEWIS (*Oreg. Cooper. Work, Dept. Int. U. S. Reclamation Serv., 1916, Feb., pp. 91, pls. 24*).—This report, prepared in cooperation with the State of

Oregon, "deals with irrigation possibilities of the Harney basin region, but more especially with the development of Harney Valley and Silver Creek Valley. . . .

"The features to which the Harney report has special reference are (1) irrigation development in Harney Valley by the storage and use of water from Silvies River to include, first, the higher development of approximately 60,000 acres gross area of land now under a crude flood system of irrigation from Silvies River, by complete storage control and a more scientific use of their water supply; second, the irrigation of approximately 40,000 acres additional land not now reached by Silvies River diversions, through storage of water now wasted; and (2) Blitzen Valley development and the possibility of using Blitzen River water for the irrigation of a part of Harney Valley, together with the possible drainage and irrigation of a part of Malheur Lake bed. . . .

"The features to which the Silver Creek report has special reference are (1) irrigation development of new lands in Silver Creek Valley and Warm Springs Valley by the storage and use of water now wasted from Silver Creek into Harney and Silver lakes, and the higher development of lands already irrigated; and (2) the possibilities of further development in Warm Springs Valley by pumping and storage, to promote a better utilization of the Warm Springs flow."

**Artesian water for irrigation in Little Bitterroot Valley, Montana, O. E. MEINZER** (*U. S. Geol. Survey, Water-Supply Paper 400 B (1916), pp. 9-37, pls. 4, figs. 4*).—This paper deals with the physiography and geology of an area of about 385,000 acres in northwestern Montana and reports an investigation of the occurrence, head, yield, and quality of the artesian water in the area, with special reference to its use for irrigation.

"The principal artesian-water bed lies about 300 ft. below the lake plain, or somewhat more than 200 ft. below the level of Little Bitterroot River. . . . Flowing wells can be obtained over about one-fifth of Little Bitterroot Valley. . . .

"In general the level to which the water from the artesian bed rises is considerably above the water level in dug wells that end at higher horizons. On the bottom lands, where the water table nearly coincides with the river level, the difference is greatest and amounts to a maximum of about 70 ft. Under the lake plain at some distance from the river the water table is considerably above river level, and the difference is not so great. In some places where there is perched water . . . the water table may stand higher than the level to which the artesian water will rise. . . . The flowing wells in Little Bitterroot Valley interfere with each other, the effect being most noticeable in wells with slight head when other wells are drilled near by at considerably lower levels. . . .

"The ground waters in Little Bitterroot Valley are not highly mineralized, the samples examined ranging in total dissolved solids from 180 to 480 parts per million. They are nearly all sodium carbonate waters, and most of them have an odor of hydrogen sulphid, but they differ considerably in mineral content and in this respect fall into two or more groups. The deep artesian waters . . . are very low in calcium and magnesium and relatively high in sodium; they are relatively high in bicarbonate, moderate in chlorin, and very low in sulphate. . . . A notable feature of the artesian water is its high temperature. The water from a few of the wells is hot, though that from other wells has a normal temperature or a temperature slightly above normal. . . .

"Jetting or hydraulic drilling rigs are now used in Little Bitterroot Valley and are well adapted to the conditions that prevail there. In those rigs water pumped down through hollow drill rods comes up on the outside and cutting drill bits are operated by the spudding method. . . . In 1915 the prevailing

prices, including casing, were about \$1 per foot for wells with 3-in. casing, \$1.25 for wells with 4-in. casing, and \$1.50 for wells with 5-in. casing. . . .

"Development of irrigation supplies from flowing wells is practically limited to the river bottom lands and the lowest bottom lands in the Hot Springs Creek drainage basin. Artesian supplies can be obtained on the bottom lands in considerable quantities at low cost, but on the higher lands in only small quantities and at very high cost for irrigation."

The alkali content of irrigation waters, R. STEWART and C. T. HIRST (*Utah Sta. Bul. 147 (1916), pp. 3-18, fig. 1*).—Analyses are reported of samples of water from six streams in Utah, showing the average amounts of the various salts added to the soil by an acre-foot of irrigation water as given in the following table:

*Average amounts of salts added per acre by 1 acre-foot of irrigation water.*

Name of stream.	Number of analyses.	Total salts.	Sodium.			Calcium.	Magnesium.		
			Nitrate.	Chlorid.	Sul-phate.	Bicar-bonate.	Bicar-bonate.	Chlorid.	Sul-phate.
		Pounds.	Pounds.	Pounds.	Pounds.	Pounds.	Pounds.	Pounds.	Pounds.
Price River.....	4	2,119.5	3.3	8.1	219.6	840.9	388.2	12.2	548.1
Huntington Creek.....	2	1,609.5	7.3	2.7	250.3	816.1	191.7	25.8	463.9
Coal Creek.....	3	902.9	3.1	59.9	76.1	601.9	121.6	16.3	286.2
Sevier River.....	10	3,272.4	22.0	646.8	121.4	881.4	116.1	74.8	817.6
Ferron Creek.....	1	1,990.0	10.9	6.3	144.1	1,014.5	106.0	.....	666.3
Emery Creek.....	1	1,055.0	8.2	.0	.0	688.0	179.0	10.3	138.7

The following conclusions are drawn:

"The mere determination of the total salts present in irrigation water is not adequate in judging the quality of the water for irrigation. The determination of total salts is valuable as a check on the analysis.

"A large part of the soluble salts of irrigation water consists of the harmless bicarbonates of calcium and magnesium. In some instances these salts constitute 50 per cent of the total amount present. The soluble salts present in irrigation water vary from time to time due to concentration by evaporation, to drainage from the surface soil during storms, and to seepage from the irrigated lands and canals.

"The waters of Price River and Huntington Creek are highly charged with harmful alkali salts and must be used very judiciously on the heavy clay soils of Castle Valley, which are already heavily charged with sulphates of sodium and magnesium. The waters of Coal Creek are excellent for irrigation since they contain only minimum quantities of harmful salts. The economical use of such water will not add excessive quantities of harmful alkali salts to the soil. The waters of the Sevier River are heavily impregnated with the harmful chlorids and sulphates of sodium and magnesium. The waters of this stream are such that their continued use without artificial drainage on the heavy clay soils of Millard County is likely to cause trouble. The waters of all the streams examined are free from sodium carbonate or black alkali, possibly due to the fact that all the streams traverse country rock which is rich in deposits of gypsum."

Tests of irrigation pumping plants, R. H. CAFES. (*Jour. Electricity, 37 (1916), No. 21, pp. 394, 395*).—The results of over 300 separate tests of irrigation pumping plants made in California during 1913 to 1916 are reported, together with the results of tests of typical plants. A summary of the results is given in the table following.

## Summary of results of tests of irrigation pumping plants.

Type of pump.	Size of pump.	Mean discharge, miner's inches.	Mean total lift.	Number of tests.	Mean efficiency of pump.	Mean overall efficiency of plant.	Mean miner's in. pumped per kw. of input per 100 ft. lift.	Kw. hours used to lift 1 acre-foot 1 ft.

Experiments with submerged orifices and tubes, T. C. ROGERS and T. L. SMITH (*Engin. News*, 76 (1916), No. 18, pp. 825-827, figs. 3).—Experiments conducted at Cornell University on the flow of water through orifices 6, 8, and 10 in. square under heads up to 2.2 ft. are reported. The length of the tube was varied, but square edges at the entrance were used throughout.

“Curves were plotted between discharge coefficient and head for each length of tube and also between average discharge coefficient and length of tube, the latter being expressed as the ratio of tube length  $L$  to the side of the square orifice  $D$ . The curves plotted showing variation of discharge coefficient with head indicate that in most cases there is a slight increase in coefficient with higher heads. This increase is not pronounced, however, except in one or two curves, and in some cases there seems to be a decrease in the coefficient with higher heads. . . .

“The general conclusion may be drawn from these experiments that annexing a tube to a submerged square orifice will greatly increase its flow under a given head until the length of tube is equal to about 1.5 times the side of the square. A longer tube will not decrease the flow, unless the friction is large, but it will not materially increase it. For free discharge into the air the coefficient does not vary, but remains at about 0.61, whatever the tube length. This value is about 0.67 per cent greater than the submerged sharp-edge coefficient, and corresponds to the submerged coefficient for  $L/D = 0.05$ . From this it follows that, given a square orifice with a tube attached and a fixed head of water upstream, a greater quantity may be made to flow through the orifice by submerging the downstream side than will flow if the orifice discharges into the air. This fact was verified by experimentation.”

The significance of streptococci in water supplies, W. G. SAVAGE and W. J. READ (*Jour. Hyg. [Cambridge]*, 15 (1916), No. 3, pp. 334-351).—Experiments with deep-water supplies, including samples from springs and deep wells, and with surface-water supplies, including samples from shallow wells, are reported. The purpose was to determine the relation of the presence or absence of streptococci to the quality of the water.

It was found that the results of analyses studied in bulk and the results of detailed consideration of individual supplies were essentially the same. The absence of streptococci is considered of less significance than their presence, and even their absence from a considerable bulk of water is not accepted, to the same extent as the absence of *Bacillus coli*, as reliable evidence of the freedom from serious contamination of the water at the time of sampling. Absence of streptococci is, however, considered a point in favor of the purity of the water.

“Standards for permissible number of streptococci broadly correspond to similar numerical standards for *B. coli*, but are of less significance and reliability.” While it is thought that not enough is known about the varying vitality and distribution of streptococci to say whether the presence of certain strains may or may not be disregarded as evidence of excretal contamination, it is concluded to be in general reliable to assume that streptococci in large numbers are only present in waters from unsatisfactory sources.

Results and conclusions from a year's operation of the activated sludge sewage treatment plant of Milwaukee, T. C. HATTON (*Engin. and Contract.*, 46 (1916), No. 19, pp. 407-409).—The results of experiments on securing activated sludge, aeration, effect of low temperatures, sedimentation, and sludge disposal are reported. With reference to sludge disposal it is concluded that there is no difficulty in reducing the Milwaukee sludge to a marketable low-grade fertilizer at less than its value. See also a previous report of experiments (E. S. R., 35, p. 188).

Public road mileage and revenues in the New England States, 1914 (U. S. Dept. Agr. Bul. 388 (1917), pp. 74).—This is a compilation showing the mileage of improved and unimproved roads, sources and amounts of road revenues, and bonds issued and outstanding, and contains a description of the systems of road administration, fiscal management, and other factors affecting road improvement in each State.

Report of the State Commissioner of Highways [of New York], E. DUFFEY (*Rpt. State Com. Highways, N. Y., 1915, pp. 939, pls. 49*).—This is a report of the work and expenditures on highway construction, maintenance, and repair in New York for 1915.

Proposed motor-truck loads for highway bridges, O. W. CHILDS (*Engin. News*, 76 (1916), No. 19, pp. 898, 899, fig. 1).—It is stated that motor trucks are the proper form of concentrated loads to specify in the design or investigation of rural highway bridges. “A typical truck is assumed to have two axles spaced 10 ft. on centers, with the two wheels on each axle spaced 5 ft. on centers. This truck covers a space 9 ft. wide by 20 ft. long, symmetrical about the truck center. One-third of the weight is on the front axle, two-thirds on the rear axle. With this standard size and distribution the capacity may be definitely and simply expressed as the total weight in tons of the loaded truck.” Diagrams giving maximum shears and moments covering the range from 5- to 24-ton trucks and spans up to 50 ft. are given.

The following table for 10-ton trucks may be used for any weight, as the values vary in direct ratio with the weight.

## Maximum shears and bonding moments for typical trucks.

"Bridges on improved roads should as a rule be designed for 15-ton typical trucks, but other capacities may be necessary for special conditions. . . . In general, impact allowance should not be less than 30 per cent of the static stress, but it should be varied to fit conditions."

Tractive resistances to a motor delivery wagon on different roads and at different speeds, A. E. KENNELLY and O. R. SCHURIG (*Proc. Amer. Inst. Elect. Engins.*, 35 (1916), No. 6, pp. 1011-1039, pl. 1, figs. 17; *Mass. Inst. Tech., Elect. Engin. Dept., Research Div. Bul. 10* (1916), pp. 1011-1039, pl. 1, figs. 17; *abs. in West. Engin.*, 7 (1916), No. 11, pp. 434, 435, fig. 1).—The results of an investigation conducted at the Massachusetts Institute of Technology on the tractive resistance of asphalt, wood block, brick block, granite block, water-bound macadam, cemented joint granite block, tar macadam, cinder, and gravel pavements in conditions varying from extremely poor to good are reported.

The vehicle used was a worm-drive single-reduction electric truck having a capacity of 1,000 lbs. The overall length of the frame was 168½ in., the width 35 in., the wheel base 107½ in., and the wheel gage 58 in. Solid-rubber demountable tires measuring 2½ by 36 in. were used on all four wheels. The truck was equipped with a direct-current series-motor. The length of runs in the road tests ranged between 400 and 2,600 ft.

It was found that "the overall efficiency of the test-truck mechanism, between battery terminals and rear-wheel treads, reached a maximum value of about 78 per cent, under the most favorable conditions. The mechanical efficiency of transmission from motor shaft to rear-wheel treads, for the truck tested, shaft-driven through a single-reduction worm gear, was found to be as high as 90 per cent.

"Tractive resistances are most conveniently expressed as an equivalent grade; that is, a level road of definite tractive resistance may be regarded as a road of zero tractive resistance, but rising uniformly  $x$  units in 100 units of road length, or having an equivalent grade of  $x$  per cent. Under the conditions of these tests, the tractive resistance on level roads, in the absence of wind, is composed of (1) displacement resistance, (2) impact resistance, and (3) air resistance.

"The displacement resistance varied from 0.85 per cent equivalent grade for a hard, smooth asphalt or bituminous concrete to 1.6 per cent for a soft tar-

macadam road, and was practically constant, for all speeds considered, on any given road. The impact resistance increases with the velocity, with the total weight of vehicle, and with increasing road-surface roughness. In these tests the impact resistance of good asphalt or bitulithic or other smooth pavement was practically negligible, and reached its highest values on granite-block roads with sand-filled joints, and on badly-worn macadam pavements. The rate of increase of impact resistance with speed was most marked on the roughest roads.

"At the vehicle speed of 20 km. (12.4 miles) per hour, the air resistance for the vehicle tested, assumed to be dependent only on the speed, was roughly 0.11 per cent equivalent grade; that is, from 4 per cent of the highest to 12.5 per cent of the lowest total tractive resistance.

"The following pavements are enumerated in the order of their desirability for vehicle operation from the point of view of tractive resistance at 20 km. per hour, as found in this investigation: Asphalt, wood block, hard, smooth macadam, brick block, granite block with cement-filled joints, cinder, gravel, and granite block with sand-filled joints.

"The equivalent grade at 20 km. per hour of a badly worn macadam road was found to be nearly three times as great as that of the best asphalt road tested. This means, at this speed, a consumption of energy at wheel treads of nearly three times as much on level, poor macadam roads as on level, good asphalt roads. Increasing the gross weight of the vehicle by 12 per cent through load was found to have no effect on tractive resistance within the observed speed limits for smooth roads in good condition; but on rough roads, a distinct increase in tractive resistance with this extra weight was observed. The presence of a layer of dust, say 1 cm. thick, on a fair macadam road, was found to increase the equivalent grade of tractive resistance at all tested speeds by about 0.15 per cent. A freshly tarred, and therefore soft, tar-macadam road was found to have an increased equivalent tractive resistance at substantially all tested speeds of about 0.5 per cent. The tires in this case sank about 0.8 in. into the roadbed, the gross car weight being 4,710 lbs. The total range of tractive resistance equivalent grade covered in the tests was from 0.93 per cent on the best asphalt road at lowest speed to 2.7 per cent on the worst macadam road at nearly the highest speed."

**First national farm tractor directory**, compiled by C. E. STONE (*New York: The Agricultural Press, 1916, pp. 8*).—This is a complete list of farm tractors, their manufacturers, horsepower, type, traction, and other particulars.

**Modern systems of independent lighting and heating** (*Nature [London], 96 (1916), Nos. 2410, pp. 522-524, figs. 5; 2411, pp. 552, 553, figs. 3; 2412, pp. 577, 578, fig. 1*).—Oil, oil gas, petrol air gas, acetylene, and electric lighting systems for country homes are described and illustrated.

## RURAL ECONOMICS.

**The farmer's labor income**, P. L. VOGT (*Amer. Econ. Rev., 6 (1916), No. 4, pp. 308-322*).—After discussing the data available from the various studies in connection with the Office of Farm Management of the U. S. Department of Agriculture as to the farmer's labor income and additional information as furnished by the Census, the author concludes as follows:

"The data presented indicate that, while at the present time labor incomes of farmers compare favorably with those in urban industries, the institution of private ownership of land does not offer much hope for further increase of these incomes unless the system of owner operation can be preserved. Laborers are evidently not benefiting by the economic changes taking place. Tenants

are nominally getting the larger incomes; but this apparent return is due to method of presentation of returns rather than to actual advantage. The uniformity of labor incomes throughout the entire area studied indicates that private ownership of land by absentee landlords who reap the benefit of such ownership, even though absent in the neighboring village, is bound to become a question of supreme importance in the future. . . .

"The problem of farm incomes is not now a serious one as related to social welfare in the country; but if present tendencies continue it is bound to be a serious one for those actually living in the country in the future. If one-half or one-third of the wealth produced on a given farm is to go to others than the operator; if farm labor is to increase because of the lack of opportunity to gain a foothold, due to high land values; then we must expect that the great central valley, one of the greatest agricultural sections of the world so far as resources is concerned, will be doomed to bear a burden that will breed discontent; that will drive our young men and women from the country; and will bring to America problems that now confront other nations in which statesmen recognize that a good income for farmers and ownership operation are essential to national welfare."

Labor income does not determine true profits, J. I. FALCONER (*Agr. Student*, 23 (1916), No. 2, pp. 104-106).—The author considers that "labor income is a fair basis upon which to compare one farm with another, but it does not afford a fair basis for comparison between the profits of farming and those in other occupations. It is a good basis upon which to compare two farms in a community, one operated, for example, as a grain farm, the other operated as a live-stock farm, or with which to compare a corn and hog farm with a dairy farm. But it is not a measure of the profits in agriculture, nor would the average labor income of a farm for a series of years be a criterion of the size of the estate which a farmer would probate at the time of his decease."

Farm profits (and factors influencing profits) on 370 potato farms in Monmouth County, New Jersey, F. APP (*New Jersey Stat. Bul.* 294 (1916), pp. 3-103, pls. 8, figs. 10).—Among the conclusions arrived at from this study, conducted in cooperation with the Department of Conservation and Development of New Jersey and the Bureau of Soils of the U. S. Department of Agriculture, are the following:

"The average labor income for the Monmouth County potato farms included in this survey is \$842. The cash tenants have the largest average labor income of \$938, while the owners have \$917, and share tenants \$739. Forty-five per cent of the potato farms are operated by tenants. Cash renting is most profitable for the tenant who is a good farmer. . . . The average farm investment for the owners is \$17,673, for the share tenants \$3,369, and for the cash tenants \$3,085.

"The farm profits increase with the increase of crop acres per farm for both owner and tenant farms. The larger farms are far more efficient in the use of man, horse, and machinery labor than are the smaller farms. . . . Farm and crop acre values decrease as size increases for all farms regardless of tenantry. . . . The average sized farm for the owners is 73 crop acres, and for the tenants 87 crop acres. . . .

"The acre cost of producing potatoes is \$85.15. The cost per barrel is 92 cents. Farmers producing 60 barrels or less per acre lose money. No class of farmers are raising higher yields of potatoes than are profitable. . . . The larger the proportion of crop acres in potatoes the greater is the labor income. . . . Lack of rotation is not decreasing potato yields, and live stock above what is needed for the farmer's personal use is not profitable on most farms. . . . Diversification lowers profits on these farms.

"The proportion of crop acres in potatoes decreases with distance from the railroad. After a distance from the railroad of four or more miles has been reached, potatoes show a low return. . . . Cooperative buying and selling has proved very successful in this region."

Factors affecting methods of farm management in the North Island, J. BROWN (*Jour. Agr. [New Zeal.], 13 (1916), No. 1, pp. 1-16, pl. 1, figs. 2*).—The author summarizes his observations regarding farm management in this community as follows:

"Good pasture is the mainstay of the North Island farmer. Most good pastures may be further improved in nutritive value by periodic applications of crushed limestone. Inferior pasture everywhere should be renewed by liming, cropping, manuring, and re-grassing after a second application of crushed limestone. . . . On light land these successive stages of improvement should automatically bring about a rotational system, including growth of oats, inexpensive forage crops, and pastures of longer or shorter duration, according to circumstances. If lucern can be grown, the maximum of profits can not be realized without it. Beyond a very narrow limit, profits recede as cultivation extends and pasture areas are reduced."

[Agricultural laws of North Dakota] (In *Compilation of Laws of the State of North Dakota Governing Railroads [etc.]*. Bismarek: Bd. R. R. Comrs., 1915. pp. 93-109).—Among the laws included in this compilation are those relating to cooperative associations, grain warehouses, and commission merchants.

The Federal Farm Loan Act (*U. S. Treas. Dept., Fed. Farm Loan Bd. Circ. 4 (1916), pp. 29*).—This circular contains the complete text of the act.

Digest of the Federal Farm Loan Act (*New York: Guaranty Trust Co., 1916, pp. 16*).—This digest endeavors to give a comprehensive idea of this act by pointing out its salient features.

[Agricultural credit in British India and Netherland East Indies], J. DOUIE and H. C. ALTING (*Trans. 3, Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 95-124*).—The authors describe the types of credit institutions, the problems in connection with their establishment and development, the methods of management, and some of the results obtained.

[Annual reports of the marketing commissioners], J. F. SMITH, W. E. McTAGGART, and R. C. ABBOTT (*Brit. Columbia Dept. Agr. Ann. Rpt., 10 (1915), pp. R54-R73, R126, R127, pls. 6*).—These reports relate to the work of the marketing commissioners in western Canada and describe their activities in assisting in the marketing of fruit and vegetables, the standardization of packages, and the reorganization of city markets. The reports also indicate the size of packages preferred by the trade and the size of boxes and crates used in marketing fruits and vegetables.

Relation between primary market prices and qualities of cotton, F. TAYLOR (*U. S. Dept. Agr. Bul. 457 (1916), pp. 13*).—This report is the result of a survey made in 73 towns located in 9 cotton-growing States, including the examination of 38,000 representative samples, to determine whether, in the same market, cotton was purchased on averages, all grades bringing the same price.

The report indicates that from such evidence as was gathered either higher grades are being priced too low or that the lower grades are bringing prices above their value, or that a combination of the two is true. The average price paid for cotton of  $\frac{3}{4}$ -in. staple was as high as for 1-in. staple. It also appears that in the eastern belt higher prices are being paid, due to the proximity to the cotton mills, absence of most of the middlemen, and to the facts that primary marketing conditions are superior, storage houses are more generally available, money rates are comparatively lower, and competition probably exists to a greater degree than in the West.

In order to improve the quality of the cotton and to obtain its true worth, the author recommends that the farmer be convinced of the importance of producing good staple and of care in picking and housing it, and that adequate but not excessive covering for the bale be supplied to protect the lint. He considers that proper storage after ginning would prevent the country damages from assuming such large proportions. He also recommends the organization of cooperative associations for the proper handling and marketing of cotton.

**Advertising the apple**, F. C. SEARS (*Mass. Agr. Col. Ext. Serv. Bul. 10 (1916)*, pp. 3-20, figs. 8).—This publication points out methods of advertising and agencies which might be interested in an advertising campaign and the part which each one would be expected to play. A number of typical illustrations are included.

**Minnesota, the center of northwestern agricultural development.—Saint Paul, the northwestern market for diversified farming** (*[St. Paul]: St. Paul Assoc. Com., 1916*, pp. 42, figs. 29).—This publication was compiled for presentation to the Federal Farm Loan Board, and sets forth the advantages of St. Paul as the agricultural and financial center for the States of Minnesota, North Dakota, South Dakota, and Montana.

**Minneapolis "the market of the northwest"** (*Minneapolis: Minn. Civic and Com. Assoc. [1916]*, pp. 166, pl. 1, figs. 90).—This report, compiled for presentation to the Federal Farm Loan Board, sets forth the advantages of Minneapolis as the center through which the Northwest sells its produce, purchases its supplies, and carries on its banking business.

**[Raleigh as the location of a Federal farm loan bank]**, W. A. WITHERS (*Raleigh, N. C.: Com. Representing Raleigh, 1916*, pp. 2+59, figs. 18).—This report points out the advantages of Raleigh as a center of agricultural production and the rural interests of North Carolina and the surrounding States, and the reasons for the establishment of a Federal farm loan bank in that city.

**[Agriculture in North Carolina]** (*Univ. N. C. Rec., No. 140 (1916)*, pp. 93).—This is a report of the North Carolina Club, which comprises the students and members of the faculty of the University of North Carolina who are studying conditions in their State. It contains a series of papers presented before the club relating to the natural resources of the State.

**Reports from the seed and plant distribution** (*Alaska Stas. Rpt. 1915*, pp. 82-93, pls. 5).—The usual extracts from letters of settlers and other persons, telling of their success with various crops and live stock and describing the possibilities and drawbacks in Alaska, are presented.

**Agricultural statistics, Ireland, 1916**, T. BUTLER (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1915-16*, pp. 29).—This report includes a summary statement by counties and provinces of the area devoted to the principal crops and the number of live stock.

**[Agricultural statistics in Germany]** (*Viertelj. Statis. Deut. Reichs, 25 (1916)*, No. 2, pp. 11. 43-11. 73).—These pages contain statistical data showing for the minor subdivisions the number of the various kinds of live stock and the area and production of the principal crops for 1915, with comparative data for earlier years.

**Agriculture in India**, J. MACKENNA (*Calcutta: Govt., 1915*, pp. III+106, pl. 1).—The author gives a brief historical treatment of the development of agriculture in India, describes the establishment of the Agricultural Research Institute at Pusa, and the organization and work of the provincial departments of agriculture. He also discusses the distribution of the various agricultural crops and their relation to the national development of the country.

## AGRICULTURAL EDUCATION.

Report of agriculture in the high schools of Michigan, W. H. FRENCH (*Mich. Agr. Col., Dept. Agr. Ed. Bul. 16 (1916), pp. 20, figs. 12*).—This is a report on the progress of agricultural instruction in the high schools of Michigan. It discusses the plan of the courses, special educational features or community work, summer employment of the agricultural teacher, special summer projects, cooperation with the county agent, etc. The agricultural units, which require 25 per cent of the student's time, consist of botany in the ninth grade, farm crops and horticulture in the tenth, animal husbandry in the eleventh, and soils and farm management in the twelfth.

In 1915-16, 44 high schools employed college-trained instructors, and 12 employed instructors with less than college training; 14 high schools have developed full four-unit courses, 12 gave four units of work alternating the last two years, and 19 gave two-unit courses. The number of students enrolled in agricultural subjects was 2,574; 140 students graduated from 4-year courses in agriculture; 600 students conducted summer-home projects, including the raising of corn and potatoes, keeping records of a dairy herd, pruning, spraying and renovating orchards, and raising poultry and swine; 1,054 conducted home-garden work, and while in some places school gardens were conducted on the community plan, individual home gardens are proving most satisfactory. Fourteen instructors were employed for the 12 months in the year, and 19 gave instruction in the elementary grades.

Twelve high schools introduced the agricultural course in 1916. Among the special features of community work undertaken by various agricultural instructors may be mentioned special Saturday and evening classes for rural teachers; evening classes in agriculture and chemistry for farmers; a farm survey along the lines of actual conditions in farm management; a township live-stock census; a special course in dairying for farmers; and, in cooperation with the agricultural college, the distribution of pure seed to farmers, demonstration work, and the organization of horticultural societies and live-stock associations.

A list of the schools and teachers giving instruction in agriculture in 1916-17 is included.

The work of the college of agriculture, E. B. COPELAND (*Philippine Agr. and Forester, 5 (1916), No. 1, pp. 36*).—This is a detailed report on the work of instruction, demonstration, and investigation in botany, chemistry, entomology, agricultural engineering, agronomy, and animal industry, and on the personnel, land and buildings, and equipment of the college of agriculture at Los Baños.

The Agricultural Instruction Act (*Agr. Gaz. Canada, 3 (1916), No. 9, pp. 776-780*).—This article gives the text of the agreement entered into between the Minister of Agriculture for Canada and the minister of agriculture of each of the nine Provinces of the Dominion under the provisions of the Agricultural Instruction Act setting forth the appropriation to each Province and the work to be undertaken for the fiscal year ending March 31, 1917. It is shown that of the total appropriation of \$1,000,000 nearly \$100,000 will be devoted to agricultural instruction in the rural and higher public schools, about \$259,000 for agricultural colleges and schools, \$20,000 for veterinary colleges, and about \$46,000 for women's work.

Agricultural education and live stock improvement in Wales (*Jour. Bd. Agr. [London], 23 (1916), No. 3, pp. 260-263*).—An account is given of the development of agricultural education in Wales in connection with local education authorities and in the agricultural departments of the agricultural colleges since 1911-12.

In consequence of the Development Fund the year 1912-13 marked the beginning of a new era in the history of agricultural education in Wales as regards public administration and financial assistance. Prior to 1912-13 the cost of the work was practically borne by the counties themselves, their total expenditure for the three years ended March 31, 1912, averaging \$30,054, while the agricultural colleges at Aberystwyth and Bangor each received \$5,832, and the latter also \$1,215 for forestry instruction. For the year ended March 31, 1915, the total estimated county expenditure was \$60,040, that to Aberystwyth college \$12,670, and that to Bangor college \$20,042.

The farm institute scheme became operative in the Welsh counties generally in 1914-15. Only two counties, Carnarvon and Monmouth, have taken steps to provide special institutions for agricultural instruction, the other 11 counties deciding to continue to work, for the time being at least, in direct association with the agricultural departments of the two colleges as before. The county schemes vary somewhat in character, but generally provide for (1) courses at local centers in agriculture, horticulture, dairying, poultry management, veterinary hygiene, and other subjects conducted by a staff employed directly by the county or through the agricultural department of one of the colleges, (2) field experiments and demonstrations in manuring, new varieties of crops, seed mixtures, etc., and (3) systematic courses in agriculture and dairying for farmers' sons and daughters, aided by scholarships and exhibitions at either one of the university colleges or county institutions where the latter exist. The additional sums to the agricultural departments of the colleges have made more scholarships available, they now incur no expenditure for purely county work, and they have appointed special officers to give technical advice to farmers and to investigate local problems, live-stock officers, and advisers in agricultural botany and chemistry.

**Instruction in light farm work and milking for women and children** (*Jour. Bd. Agr. [London]*, 23 (1916), No. 3, pp. 264-271).—Brief summaries are given indicating the provision made by various county authorities for instruction in light farm work and milking for women and children in England and Wales. The instruction is given at agricultural colleges and farm schools, farm institutes, approved farms, etc., and varies in length from two to nine weeks.

**Farm mechanics** (*Agr. Gaz. Canada*, 3 (1916), No. 8, pp. 731-739, fig. 1).—This is a series of articles containing an account of the instruction in farm mechanics, including outlines of courses of study, methods of instruction, equipment, examinations, etc., in the Nova Scotia College of Agriculture, MacDonald College, Ontario Agricultural College, Manitoba Agricultural College, Saskatchewan College of Agriculture, and the Alberta schools of agriculture.

**The kingdom of the plants**, C. A. NORCROSS and P. A. LEHENBAUER (*Agr. Ext. Univ. Nev. Bul.* 8 (1916), pp. 23, figs. 20).—This bulletin comprises the first four lessons of a series of 16 in an extension course in gardening for boys' and girls' clubs. These lessons are devoted to definitions of terms in the study of plant life, seeds and how they germinate, plant structure and growth, and the work of plants. Experiments and a list of questions to test the pupils' knowledge of plants are included.

**Twenty lessons in domestic science**, MARIAN C. FISHER (*Author*, 1916, pp. 108, figs. 19).—This is a condensed home study course in domestic science comprising 20 lessons dealing with food principles, the functions, classification, assimilation, and composition of food, dietary standards, methods of cooking, and recipes and kitchen equipment. A list of Farmers' Bulletins of this department, reference tables, pronunciations and definitions, and other miscellaneous data of value to the housekeeper are appended.

A series of lessons in cooking and household management, MYRTLE HULLINGER (*Springfield, Ohio: Author, 1916, pp. 416, figs. 5*).—Thirty-eight lessons in cookery and care of the house are outlined by the head of the department of domestic science of the high school in Springfield, Ohio.

An outline on the history of cookery, ANNA BARROWS, BERTHA E. SHAPLEIGH, and ANNE D. BLITZ (*Teachers Col. [N. Y.] Bul. 11, 6. ser. (1915), pp. 36*).—This outline on the history of cookery is arranged in four parts, viz. prehistoric, ancient, medieval, and modern times, with special references to literature for each part, and a general bibliography, together with suggested topics for individual investigation, either for papers or for class development, at the end of the bulletin.

Clothing for women, LAURA I. BALDT (*Philadelphia and London: J. B. Lippincott Co., 1916, pp. XIV+454, pls. 8, figs. 262*).—This manual for the school and home presents the fundamental principles involved in and practical working directions for the selection, design, and construction of clothing for women. The construction of garments is approached from the standpoint of those who have had instruction in elementary sewing, but for others a review of the fundamental stitches and some simple processes have been included in the section on undergarments. Among the subjects treated are clothing budgets and buying, the theory and use of color, and pattern making. A chapter is devoted to instruction to (1) teachers on the use of the text, including the use of illustrative material, suitable equipment, teaching material, and method of instruction, and (2) the home woman and dressmaker.

Shelter and clothing, HELEN KINNE and ANNA M. COOLEY (*New York: The Macmillan Co., 1913, pp. XV+377, pl. 1, figs. 159*).—This textbook, intended for high and normal school students, as well as for the home maker, deals with the home, its ideals in organization, its sanitation, decoration, and furnishing; also with textiles, sewing, dressmaking, economics of dress, and millinery. Practical exercises are appended to each topic and suggestions are offered to teachers on presenting the text.

Food and health, HELEN KINNE and ANNA M. COOLEY (*New York: The Macmillan Co., 1916, pp. VI+312, pl. 1, figs. 138*).—This is an elementary textbook of home making, written in story form. It "treats largely of food problems, including something of raising food and selling it, in addition to the preparation of food at school and at home. Such topics as the water supply, disposal of waste, and other sanitary matters are woven in with the lessons on nutrition and cookery." The work is outlined in 29 lessons, including exercises and problems and a number of simple recipes.

A course in household arts, I, LORETTO B. DUFF (*Boston: Whitcomb and Barrows, 1916, pp. XVI+301, figs. 21*).—This course is the outgrowth of a course in household arts prepared in 1902 and in general use for many years in the Boston public schools of cookery. It consists of two parts, each containing material for one lesson a week for a year, thus covering the essentials of the course in two years. This book, or part 1 of the course, is designed primarily for beginners, and deals with the fundamental principles underlying the methods employed in cookery and other household arts, including only simple experiments which can be performed with utensils found in the ordinary school kitchen.

### MISCELLANEOUS.

Report of Alaska Stations, 1915 (*Alaska Stas. Rpt. 1915, pp. 100, pls. 19*).—This contains the organization list and a report of the several lines of work

carried on during the fiscal year ended June 30, 1915. Meteorological data and accounts of the extensive tests with field and garden crops, live-stock operations, and other lines of work are abstracted elsewhere in this issue.

**Twenty-seventh Annual Report of North Dakota Station, 1916** (*North Dakota Sta. Rpt. 1916* [pt. 1], pp. 21, figs. 3).—Part 1 of this report contains the organization list, a report of the director, and a financial statement as to the Federal funds for the fiscal year ended June 30, 1916. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Monthly bulletin of the Western Washington Substation** (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 4 (1916), Nos. 9, pp. 16, figs. 3; 10, pp. 16, figs. 3).—These numbers contain brief articles on the following subjects:

No. 9.—The Winter School, by W. A. Linklater; The Use of Fertilizers to Increase Crop Production, by E. B. Stookey (see p. 425); Suggestions in Potato Growing, by J. L. Stahl; and Concerning Poultry Feed Values, by Mr. and Mrs. G. R. Shoup (see p. 473).

No. 10.—Standardizing of Land Clearing, by I. D. Charlton; Reducing the Cost of Milk Production, by H. L. Blanchard (see p. 473); Dairy Farm Cropping System, by E. B. Stookey; Rhubarb Culture, by J. L. Stahl; Canker, Chicken Pox, and Roup, by Mr. and Mrs. G. R. Shoup; A New Phase of the Raspberry Rust, by A. Frank; and Some Meat-curing Methods.

Principles on which should be established the mutual relations of experimental and extension institutions, I. V. EMELIANOV (*O Nachalakh, na Kotorikh Dolzhni Stroitsia Vzaïmootnosheniia Obshchestvennoagronomicheskikh i Opytnikh Organizatsii*. Kharkof: Kharkov. Oblast. Selsk. Khoz. Opytn. Sta., 1915, pp. 6).—The author believes that three systems of organization are possible: (1) The complete fusion of the experimental and extension institutions in program and organization; (2) the partial fusion of the institutions, with separate functions devolving on each of them; and (3) the independent organization of each and a strict distribution of functions. The vitality and value of the local extension work depends on its agreement and close solidarity with experimental studies, but it is thought that in view of the great qualitative difference in the problems and the method of work, the basis of such solidarity should be the independence of each of the institutions and a clear division of the functions of experimentation and instruction. Existing conditions in the region insure the possibility of intercourse and close cooperation of extension workers and experimenters, but it is deemed necessary to develop and maintain in the future ways and means for such cooperation. It is also thought that the district experiment stations should organize a division for the study of the economics of the husbandry of the region.

## NOTES

---

**Connecticut State Station.**—Howard F. Huber, specialist in market gardening, has resigned to accept a position in the extension service of Rutgers College.

**Iowa College and Station.**—The new animal husbandry laboratory is nearing completion. It is a one-story building 74 by 112 ft., costing about \$50,000. It has been devised especially for work in connection with the slaughtering, dressing, cutting, and curing of meats. The basement contains a 10-ton refrigerating plant, coolers, a smokehouse, refining, sausage, lard, and other by-product rooms, offices, etc. The main floor can be divided into three distinct rooms, or used as a whole for demonstration work.

The recent short course and farmer's week was more largely attended than ever before, the aggregate reaching 3,500. About 400 of these were in the junior work.

A State-wide egg laying contest is being planned by the State Poultry Breeders' Association, to be held at the college next year if sufficient facilities can be made available.

Howard C. Barker, assistant professor in dairy husbandry extension work, has resigned to engage in farming. W. G. Gaessler, assistant chief of the chemical section of the station, has been granted leave of absence until September for graduate work at the Ohio State University, during which time G. P. Plaisance will act as assistant chief. W. H. Johnson, assistant in the soils section, has been granted leave of absence until July for special graduate study at the University of Wisconsin, his work to be carried on by Knute Espe. W. G. Kaiser, assistant in the agricultural engineering section, resigned January 4.

**Kansas College and Station.**—The estimated attendance at the exercises of farm and home week, February 5 to 10, was 1,800, an increase of 500 over the previous year and representing 96 of the 105 counties of the State. An attempt was made to meet the interests and needs of all classes of visitors by arranging the program in groups under the heads of agriculture, home economics, engineering, boys' and girls' work, cream station operators and butter makers, State associations, and exhibits and contests. The exhibits of the boys' and girls' clubs and the mother and daughter canning clubs, as well as those of the college and station, attracted particular attention.

Dr. F. S. Schoenleber, for 12 years head of the department of veterinary science, has resigned effective March 1. Dr. John Patterson has been appointed instructor in veterinary medicine, beginning February 1. John L. Bayles, assistant in agronomy at the Garden City substation, has resigned to accept a position in the agricultural department of the St. Louis and San Francisco Railroad Co.

**Michigan College and Station.**—According to a note in the *M. A. C. Record*, the botanical courses for students in agriculture are to be reorganized. The freshman work is to remain substantially as at present, but following this there will be three groups of electives. The first of these, known as applied botany, will be designed for students expecting to engage in work closely associated with farm life, and will include studies of economic plants, plant reproduction, general plant physiology, diseases of economic plants and their control,

weeds and weed seeds, and grasses. The second group, designed for students expecting to teach in secondary or normal schools, will include a special teacher's course, taking up the content of a course in botany in such schools, the method of approach, equipment of the laboratory, source of material, etc. The three groups will comprise electives in technical lines, including advanced plant physiology, mycology, plant pathology and its methods, plant nutrition, plant physics, technique, cytology, and heredity.

More work is also being required in the college in English composition, and additional college credit for the subject is being allowed.

B. A. Knowles, a 1915 graduate, has been appointed instructor in poultry, effective February 3, vice W. H. Tully resigned. W. N. Clark has resigned as instructor in animal husbandry, effective March 10, to become manager of a dairy farm near Chicago. P. B. Wiltberger, instructor in entomology in the University of Maine, has been appointed instructor in entomology and assistant in the station, vice G. C. Woodin.

**Minnesota University.**—The first annual short course for agricultural editors was held at the college of agriculture beginning February 13, with an attendance of about 150.

**Nebraska University and Station.**—The attendance at the annual farmer's week is reported to have approximated 1,500. The new dairy husbandry building was dedicated during the week. The principal addresses were by President R. A. Pearson of the Iowa College, who was given the honorary degree of doctor of agriculture, and J. H. Frandsen, who spoke on The New Dairy Building and the Field of Dairy Husbandry.

T. W. Nicolet, assistant professor of landscape architecture, has resigned to become instructor in horticulture at the University of Illinois in connection with courses in design and plant materials in the division of landscape engineering. J. A. Ratcliff has resigned as assistant professor of experimental agronomy, effective April 1, to engage in farming in Oklahoma.

**North Carolina College and Station.**—The inauguration of President Wallace C. Riddick took place February 22. The principal addresses were by Dr. H. S. Drinker, Hon. Herbert Quick of the Federal Farm Loan Board, former President D. H. Hill, and President Riddick.

Plans are under way to give the seven test farms in the State the status of substations, thereby emphasizing the experimental features rather than demonstrational work in general farming. Many of the station activities with crops, animals, etc., are already carried on at these farms, and it is hoped to arrange for additional funds and equipment for their development. The Pender substation at Willard is to be devoted especially to work with truck crops, the Buncombe substation at Swannanoa is to specialize in small grain and orchard crops, and the Winona substation is to study the handling of muck soils.

R. G. Hill and S. C. Clapp, assistant horticulturist and assistant entomologist respectively, at the main station, have been transferred as assistant directors in charge of the Pender and Buncombe substations, and H. Barker has been appointed assistant director in charge of the Winona substation.

J. E. Moses, county agent in Escambia County, Alabama, has been appointed pig club agent in the extension service.

**Ohio State University.**—The enrollment for farmer's week exceeded 4,000. Farmers' associations numbering 16 met during this period.

**Pennsylvania College.**—Nickolas Schmitz, agronomist at the Maryland Station, has been appointed professor of agronomy extension beginning February 17, and Miss Martha S. Pittman, instructor in home economics extension beginning February 12.

## CONTENTS OF VOL. 36, NO. 6.

	Page.
Recent work in agricultural science.....	501
Notes.....	599

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The arsenates of lead, II, McDonnell and Smith.....	501
Yeast protein, Neuberg.....	501
The organic phosphoric acid of starch, Northrop.....	501
The occurrence of chitin and cellulose in bacteria, Van Wisselingh.....	501
The poisonous principle of poison oak ( <i>Rhus diversiloba</i> ), McNair.....	501
On the constituents of poison ivy ( <i>Rhus toxicodendron</i> ), Acree.....	502
Lignoceric acid from rotten oak wood, Sullivan.....	502
Relation between the physical and chemical constants of oils and fats, Backer..	502
Storage changes in vegetable and animal oils, Gardner.....	502
The fruit of <i>Smilax rotundifolia</i> , Rogers.....	502
The fruit of <i>Vaccinium corymbosum</i> , Harris and Thrams.....	502
The cause of the ureolytic action of soy beans, Wester.....	503
The separation of oxidase reactions from the catalase reaction, Reed.....	503
Relation of oxidase reactions to changes in hydrogen ion concentration, Reed..	503
Conductivity of solutions at different frequencies, V-VII, Taylor and Acree..	503
Effect of pressure on potential of hydrogen electrode, Loomis and Acree.....	503
Review: The preparation of conductivity water, Kendall.....	504

	Page.
A simple mercury sealed ether still, Smith and Morgan . . . . .	504
An electrically heated vacuum desiccator, Robertson and Schmidt . . . . .	504
Analysis by machinery, Sinkinson . . . . .	504
A method for the determination of nitric nitrogen, Scales . . . . .	504
The efficiency of the aeration method for distilling ammonia, Kober . . . . .	504
The separation of lithium from the other alkali metals, Palkin . . . . .	505
Method of extraction as affecting phosphoric acid in soils, Hale and Hartley . . . . .	505
Investigation of methods for determination of the soil reaction, Christensen . . . . .	505
The determination of volatile fatty acids, Voitkevich (Wojtkiewicz) . . . . .	506
Estimation of sugar in meat products, particularly extracts, Smith . . . . .	506
The determination and distribution of moisture in bread, Wessling . . . . .	506
Microscopical examination of chocolates and cocoas, Collin and Gobert . . . . .	506
The determination of gum in gum sirups, Luce . . . . .	507
New method for determination of vanillin in vanilla extract, Dox and Plaisance . . . . .	507
The use of amyl alcohol in Gerber's method, Orla-Jensen . . . . .	507
The biological method for judging the freshness of milk, Kalantarov . . . . .	507
A polariscopic determination of sugar in "condensed milk," Brooks . . . . .	508
A study of proteins in urine and their estimation, Marshall et al. . . . .	508
An aeration method for alcohol in fermentation mixtures, Dox and Lamb . . . . .	508
Distillation of cane sugar at the distillery of Oisemont (Somme), Saillard . . . . .	508
Home and farm canning, Cruess . . . . .	509
The use of pure yeast in the preparation of fruit wines, Korolev . . . . .	509
The Burma myrobalans or "panga" fruits as a tanning material, Puran Singh . . . . .	509
The conservation of pork, Kallert and Standfuss . . . . .	509
Conservation of fish by freezing, Plank, Ehrenbaum, and Reuter . . . . .	509
A method for determining the strength of paper when wet, Reed . . . . .	509

## METEOROLOGY.

The weather map: An introduction to modern meteorology, Shaw . . . . .	509
Highest and lowest temperatures of 1916 . . . . .	509
Frosts of 1916 . . . . .	510
Report of the meteorological service [of Canada], Stupart . . . . .	510
The meteorological office of Argentina, Davis . . . . .	510
The climate of France, Bigourdan . . . . .	510
The oscillation of climate in southeast Russia, Tol'skiĭ (Tolsky) . . . . .	510
Influence of the weather on the use by plants of fertilizers, Christensen . . . . .	510

## SOILS—FERTILIZERS.

Measurements of soil fertility, Jordan . . . . .	510
Concerning tillage, Burdick . . . . .	511
Soil survey of Clay County, Alabama, Taylor et al. . . . .	511
Soil survey of Clinton County, New York, Maxon and Cone . . . . .	511
The soils of Cuba, Crawley . . . . .	511
Microbiological investigation in connection with crop yields, Voitkevich . . . . .	511
Organic matter of soil.—I, Humus, humus carbon, and nitrogen, Gortner . . . . .	512
Investigations on an experimental cultivated soil, Diem . . . . .	513
Influence of pine resin and tannin on the soil, Koch and Oelsner . . . . .	513
Influence of moisture on the nitrogen changes in soils, Traaen . . . . .	513
On the nature of ammonification and nitrification, Miyake . . . . .	513
Gain in nitrogen from growth of legumes on acid soils, Fred and Graul . . . . .	514
The physiologically acid and alkaline salts and soil sickness, Aberson . . . . .	514
Vertical distribution of phosphorus in surface soil of prairies, Alway and Rost . . . . .	514
Mobilization of soil phosphoric acid under influence of bacteria, IV, Severin . . . . .	515
The influence of salts on the bacterial activities of the soil, Greaves . . . . .	515
Muck humus as a fertilizer and carrier of soil bacteria, Manns and Goheen . . . . .	516
Experiments on "humogen" (bacterized peat), Voelcker . . . . .	517
Nodule bacteria ( <i>Bacterium radicolola</i> ) in soils, Kalantarov (Kalantarow) . . . . .	517
Are spore-forming bacteria of significance in soil? Conn . . . . .	517
A possible function of Actinomycetes in soil, Conn . . . . .	518
The relation of protozoa to certain groups of soil bacteria, Hills . . . . .	518
Sterilization of the soil, Cunliffe . . . . .	518
Green manuring experiments, Voelcker . . . . .	518
Availability of potash as affected by lime or gypsum, Briggs and Breazeale . . . . .	519
Acidity of soils and lime requirements, Voelcker . . . . .	519

	Page.
Chalking: A useful improvement for clays overlying the chalk, Russell.....	519
The relation of lime to magnesia in soils, Voelcker.....	519
Influence of magnesia on wheat, Voelcker.....	519
The influence of strontium salts on wheat, Voelcker.....	520
Action of manganese, iron, and copper on the growth of plants, Vageler.....	520
Concerning the use of commercial fertilizers in 1916.....	520
Analyses of commercial fertilizers.....	520
Official report on commercial fertilizers inspected during 1914.....	521
Commercial fertilizers, Cady.....	521
Commercial fertilizers, Hills, Jones, and Anderson.....	521

## AGRICULTURAL BOTANY.

Hereditary reaction system relations, Clausen and Goodspeed.....	521
On the composition of factorial formula for zygotes, Fujii and Kuwada.....	521
Observations on inheritance of sex ratios in <i>Mercurialis annua</i> , Yampolsky.....	522
Inheritable variations in the yellow daisy ( <i>Rudbeckia hirta</i> ), Blakeslee.....	522
A tetracotyledonous race of <i>Phaseolus vulgaris</i> , Harris.....	522
Self, close, and cross fertilization of beets, Shaw.....	522
Self-pollinations and cross-pollinations in <i>Cichorium intybus</i> , Stout.....	523
Studies on the blooming of hemp, Havas.....	523
The persistence of the style on fruits, Campbell.....	523
Determinative action of enviroic factors upon <i>Neobeckia aquatica</i> , MacDougal.....	523
Plant ecology and the new soil fertility, Lipman.....	523
Growing plants in large containers under control conditions, Wright.....	524
An apparatus for aerating culture solutions, Weatherwax.....	524
Preliminary report on synthetic media, Doryland.....	524
The mechanism and conditions of growth, MacDougal.....	524
The nature of mechanical stimulation, Osterhout.....	525
Energy transformations during the germination of wheat grains, Doyer.....	525
Relation of soil moisture to transpiration and photosynthesis in corn, Yuncker.....	525
On the relation between the rate of root growth and oxygen, Cannon.....	525
The embryo sac and pollen grain as colloidal systems, Lloyd.....	526
Content of amylase in ripening seeds of horse beans, Blagovrëshchenskii.....	526
Present status of problem of effect of radium rays on plant life, Gager.....	526
The influence of ultraviolet rays on phosphorescent bacteria, Gerretsen.....	526
Influence of inorganic salts on the development of Actinomycetes, III, Münter.....	526
Note on the nitrogen nutrition of mold fungi, Brenner.....	527
Variations in nodule formation, Leonard.....	527
The physiological significance of the mycorrhizæ of trees, Petri.....	527

## FIELD CROPS.

The use of checks and repeated plantings in varietal tests, Pritchard.....	527
The mode of pollination in some farm crops, Pope.....	527
The identification of grasses by their vegetative characters, Carrier.....	527
Dry farming in Utah, Harris and Ellison.....	528
A twenty-year comparison of different rotations, Hartwell, Damon, et al.....	528
[Field crops].....	529
Field experiments, 1915.....	529
Catch crops.....	529
Forage plants.....	529
The history of Kentucky blue grass and white clover, Carrier and Bort.....	529
Corn improvement in the Philippines, Jacobson.....	529
Sea Island cotton, Orton.....	530
West Indian Cotton Conference, 1916.....	530
Flax seed for 1916 sowing.....	530
Concerning the oat crop, Hills.....	530
Observations on some degenerate strains of potatoes, Stewart.....	530
Some disappointing seed potatoes, Hall.....	531
Potatoes, Zavitz.....	531
Correlative characters of the rice plant, Jacobson.....	531
The weight of rice grains, Jacobson.....	531
An early reference to Philippine rice varieties, Jacobson.....	531
A Philippine wild rice, Jacobson.....	531
The causes of low yields of rice in the Philippines, Jacobson.....	531
Methods used to improve rice culture in the Philippine's Jacobson.....	531

	Page.
Rate of sowing nursery beds; age of seedlings when transplanted, Jacobson.....	532
Influence of area per plant on yield of grain in rice culture, Jacobson.....	532
Errors in rice fertilizer experiments, Jacobson.....	532
Consumption of rice in the Philippine Islands, Jacobson.....	532
Some observations on Chinese rice culture, Jacobson.....	532
Rye culture experiments at Pentkowo, Bieler.....	532
Triple-seeded spikelets in sorghum, Cron.....	532
Soy-bean products and their uses, Williams.....	532
[Cultural experiments with different varieties of sugar beets], Fallada.....	533
Experiments in transplanting sugar beets, Pritchard and Longley.....	533
Fertilizing of sugar beets, Gerlach.....	533
History of cane varieties in the Philippines, Hines.....	533
Tobacco growing in Ireland.....	533
The origin, characteristics, and quality of Humpback wheat, Thomas.....	533
Variations in the plants from the same head of wheat, Ewart.....	534
An effective head thrasher, Hanger.....	534
Agricultural seed.—Concerning weeds and weed seeds, Burns and Peitersen...	534
The use of sulphuric acid in combating weeds infesting wheat, Morettini.....	534
Ferrous sulphate control of hedge and wild mustard in Bavaria, Hiltner.....	535
Ragwort, M'Govern.....	535

## HORTICULTURE.

What, where, when, and how to plant, Bohlender.....	535
Round the year in the garden, Thomas.....	535
The home vegetable garden, Waid.....	535
Growing seeds for the world, Kruhm.....	535
Nitrate of soda spray for fruit bearing, Volch.....	535
Results from spraying in Nova Scotia, Sanders and Brittain.....	535
The cost of spraying, Odell.....	535
The apple as affected by dormant and seasonal pruning, Alderman and Aughter.	535
Apples: Production estimates and important varieties, Gould and Andrews.....	536
Observations on the ripening of Bartlett pears, Cruess and Stone.....	536
Navel persimmons, Coit.....	536
The common honey bee as an agent in prune pollination, Hendrickson.....	536
Inheritance in Vitis, Rasmuson.....	537
Portuguese varieties of vines, de Castella.....	537
Arsenate of lead in viticulture, Muttelet.....	537
Varietal standardization, Scott.....	537
Four years' experience with budded avocado trees, Whedon.....	537
[Cacao experiments, 1914-15], de Verteuil.....	537
Bud variations in lemons, Shamel.....	537
Notes on oranges and lemons, Davies.....	538
How to fertilize olive trees, Rolet.....	538
Manganese as cause of depression of assimilation of iron by pineapple, Johnson..	538
Soil management in cinchona culture, van Leersum.....	538
The cultivation of belladonna in California, Schneider.....	538
Possibility of commercial production of lemon-grass oil in United States, Hood..	538
What science has done and will do for floriculture, White.....	539

## FORESTRY.

Eighth annual report of the state forester.—Forestry in Vermont, Hawes.....	539
Progress report of the Forest Research Institute for 1915-16, Osmaston.....	539
The trees of Vermont, Burns and Otis.....	539
The vegetation of the New Jersey pine barrens, Harshberger.....	539
The sandalwoods of Hawaii.—A revision of the genus Santalum, Rock.....	539
The conifers and taxads of Japan, Wilson.....	539
Indian timbers used in engineering construction, Pearson.....	539
Experimental notes on the bitter oak, Ferrari.....	540
Gutta-percha, Barnard.....	540

## DISEASES OF PLANTS.

Laboratory outlines in plant pathology, Whetzel et al.....	540
Diseases of cultivated plants and trees, Masseur.....	540
Report of committee on fungus diseases, Manns.....	540

	Page.
Report of committee on fungus diseases, Manns.....	540
Cooperation in the investigation and control of plant diseases, Kellerman.....	540
[Plant diseases in Barbados], Bovell and Dash.....	540
Annual report for 1915 of the botanist, Biffen.....	541
Hydrogen ion concentration and natural immunity in plants, Wagner.....	541
Crown gall or plant cancer, Smith.....	541
North American species of <i>Allodus</i> , Orton.....	542
Some species of <i>Nummularia</i> common in Indiana, O'Neal.....	542
The genus <i>Rosellinia</i> in Indiana, Ramsey.....	542
Correlation of certain long-cycled and short-cycled rusts, Travelbee.....	542
Continuous rust propagation without sexual reproduction, Ludwig.....	542
Cereal diseases and pests, Riehm.....	542
Cereal rusts in subtropical South America, Gassner.....	542
Dependence of rusts on the stage of the host and external factors, Gassner.....	542
Oat smut in Indiana, Pipal.....	542
Leaf smut of timothy, Osner.....	543
Plant diseases affecting alfalfa, Melchers.....	543
Alfalfa crown wart in the western United States, McKee.....	543
A new disease of beets in northern France, Miège.....	543
Is cucumber mosaic carried by seed? McClintock.....	543
Peanut mosaic, McClintock.....	544
Fungus parasites of the pigeon pea, Rangel.....	544
Silver scurf of the white potato, Taubenhaus.....	544
The sweet potato "soil rot" or "pox," a slime mold disease, Elliott.....	544
The sweet potato "soil rot" or "pox" organism, Elliott.....	544
Tree wounds and diseases, their prevention and treatment, Webster.....	544
Sun scald of fruit trees, a type of winter injury, Mix.....	544
Control of pear scab, Smith.....	545
Peach scab and its control, Keitt.....	545
Grape anthracnose in America, Shear.....	545
Studies on <i>Plasmopara viticola</i> (downy mildew of grapes), Gregory.....	545
Downy mildew on direct bearers, Obiedoff, Baquero, and Pehlivanoglou.....	546
Variations in the resistance of grape to downy mildew, Ravaz and Obiedoff.....	546
Powdery mildew of grapes and control in United States, Reddick and Gladwin.....	546
Leaf spot on vines, Dobson.....	546
Chlorosis of pineapples induced by manganese and carbonate of lime, Gile.....	546
The causes of unnecessary decay in lemons, Willits.....	546
Overwintering of <i>Oidium</i> parasitic on <i>Photinia serrulata</i> , Peglion.....	546
On <i>Oidium</i> mildew on carnations, Mercer.....	547
The biology of Uredineæ on Geranium, Jacob.....	547
A new leaf spot of <i>Viola cucullata</i> , Anderson.....	547
The control of damping-off of coniferous seedlings, Hartley and Pierce.....	547
Parch blight on Douglas fir in the Pacific Northwest, Munger.....	547
The alternate hosts of the white pine blister rust, Grose.....	547
[The white pine blister rust situation], Spaulding.....	548
White pines of Lenox menaced.....	548
<i>Endothia parasitica</i> and related species, Shear, Stevens, and Tiller.....	548
Notes on some South African mistletoes and their hosts, Marloth and Drege.....	548
Some studies on Bordeaux mixture, Lutman.....	548

## ENTOMOLOGY.

Miscellaneous notes on injurious insects, Parrott and Hodgkiss.....	549
Some new or rare fruit pests, Hall.....	550
Potato insects, Webster.....	550
The insect fauna of New Jersey greenhouses, exclusive of the Coccidæ, Weiss.....	550
Cacao thrips and die-back in St. Vincent.....	550
A synopsis of the genus <i>Oxythrips</i> , Hood.....	550
A new <i>Plectrothrips</i> from Jamaica, Hood.....	550
Check list of the Hemiptera of America, north of Mexico, Van Duzee.....	550
Remarks on <i>Lygus invitus</i> , a new species and variety, Knight.....	550
The ash leaf bug, <i>Neoborus amoenus</i> , Dickerson and Weiss.....	551
Notes on cicadas from the United States with several new species, Davis.....	551
The identity of <i>Eriosoma querci</i> , Baker.....	551
<i>Monarthropalpus buxi</i> in New Jersey, Weiss.....	551
Susceptibility of eggs of <i>Aphis pomi</i> and <i>avenæ</i> to hydrocyanic acid, Ross.....	551

	Page.
Notes on the Psammocharidae, with a new species, Rohwer.....	551
The shell-bark hickory mealy bug, Hollinger.....	551
Contributions to the knowledge of the Dactylopiinae of Hawaii, Ehrhorn.....	551
The best methods of destroying lice and other body vermin, Kinloch.....	551
Notes on Anoplura and Mallophaga from mammals, Ferris.....	552
Notes on the feeding habits of adult Chrysopidae, Ripley.....	552
A new species of Exoprosopa, Cole.....	552
A new species of Tortrix of economic importance from Newfoundland, Gibson..	552
A caterpillar on the ears of wheat, Somerville.....	552
Mosquitoes and man, Jennings.....	552
New Aedes from the mountains of California, Dyar.....	552
The earliest name of the yellow fever mosquito, Knab.....	552
Eggs and oviposition in certain species of Mansonia, Dyar and Knab.....	552
Mosquitoes at San Diego, California, Dyar.....	552
The March fly in grain fields and as a pest of celery, Strickland.....	552
What is <i>Tabanus mexicanus</i> ? Knab.....	553
Two new North American Diptera, Shannon.....	553
Critical notes on Syrphidae, Knab.....	553
Further notes on Syrphidae, Knab.....	553
Notes concerning <i>Gastrophilus hæmorrhoidalis</i> , Parker.....	553
Lithohypoderma, a new fossil genus of oestrids, Townsend.....	553
Some notes concerning overwintering of the house fly at Dallas, Texas, Dove..	553
Transmission of leprosy by the house fly ( <i>Musca domestica</i> ), Marchoux.....	554
Muscoid flies from the southern United States, Townsend.....	554
Some new North American muscoid forms, Townsend.....	554
On Australian Muscoidea, with description of new forms, Townsend.....	554
Miscellaneous muscoid notes and descriptions, Townsend.....	554
Notes on the hen flea ( <i>Echidnophaga gallinacea</i> ), Illingworth.....	554
Flat-headed borers affecting forest trees in the United States, Burke.....	554
The pine bark beetle ( <i>Ips pini</i> ), Clemens.....	554
Biological notes on <i>Ceutorhynchus marginatus</i> , Frost.....	555
On some weevils attacking orchids, Champion.....	555
Some unusual orchid insects, Weiss.....	555
A survey of beekeeping in North Carolina, Carr.....	555
The control of ants in dwellings.—A new remedy, Gibson.....	555
Descriptions of various chalcidoid Hymenoptera, I and II, Girault.....	555
Nine new species of Hymenoptera, Crawford.....	556
Some new American Hymenoptera, Crawford.....	556
Descriptions of miscellaneous chalcid flies, Girault.....	556
A remarkable new genus of Encyrtidae from the West Indies, Girault.....	556
A new genus of Tetrastichini (chalcidoid Hymenoptera), Girault.....	556
The North American species of Dibrachys with a note on Uricella, Girault.....	556
A new species of Lepidopria from North America, Brues.....	556
Notes on the egg parasites of the apple tree tent caterpillar, Williams.....	556
New chalcid flies from Maryland, Girault.....	556
The occurrence of Neoderostenus Girault in North America, Girault.....	556
A new genus of omphaline eulaphid chalcid flies from Maryland, Girault.....	557
Descriptions of and observations on some chalcidoid Hymenoptera, Girault...	557
The occurrence of the genus Achrysocharelloidea in North America, Girault...	557
The red spider on cotton, McGregor and McDonough.....	557
The sexual evolution of <i>Sarcocystis muris</i> , Crawley.....	557

## FOODS—HUMAN NUTRITION.

Studies of different grades of milk in infant feeding, Washburn and Jones.....	558
Value of different grades of milk in infant feeding, Washburn and Jones.....	559
Infant feeding.—Addition of limewater to milk, Bosworth and Bowditch.....	559
Influence of rennin on gastric digestion of milk protein, Leary and Sheib.....	559
Cereal foods in the course of history, Maurizio.....	560
Milling and baking tests of Victorian wheat, Scott and Winslow.....	560
Is lysin the limiting amino acid in wheat, maize, or oats? McCollum et al.....	560
Homemade bread substitutes for diabetic patients, Williamson.....	560
Potatoes, sweet potatoes, and other starchy roots as food, Langworthy.....	560
Canned tomatoes, McGill.....	561
Determinations of preservatives in caviar, Köpe.....	561
The nutritive value of wood, Haberlandt.....	561

	Page.
The iodine content of food materials, Bohn.....	561
[Conventions of the Association of American Dairy, Food, and Drug Officials].	561
The sanitation of public markets, Armstrong.....	562
Three delicious meals every day for the farmer, Carver.....	562
The rural school lunch, Farnsworth.....	562
Typical electric range designs, Wilcox.....	562
Effect on higher animals of the sterilization of the air and food, Kianizin....	562
Studies of the gastric residuum, I, Fowler and Zentmire.....	562
Pancreatic diabetes in the dog, IV, Murlin and Sweet.....	562
Scurvy in Zhob, Baluchistan, Sheppard.....	563

## ANIMAL PRODUCTION.

Digestibility of the cell wall of wood, Haberlandt and Zuntz.....	563
Commercial feeding stuffs, 1915-16, Woods.....	563
Commercial feeding stuffs, Hills, Jones, and Anderson.....	563
Cotton-seed meal and velvet beans for fattening steers, Templeton and Gibbens.	563
Cattle feeding.—XII, Winter steer feeding, 1915-16, Skinner and King.....	564
Skim milk and milk substitutes for calf feeding, Hunziker and Caldwell.....	565
The efficiency of certain milk substitutes in calf feeding, Carr et al.....	567
Sheep feeding.—VI, Fattening western lambs, 1915-16, Skinner and King.....	568

No. 6.

---

## RECENT WORK IN AGRICULTURAL SCIENCE.

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The arsenates of lead.—II, Equilibrium in the system  $PbO$ ,  $As_2O_5$ ,  $H_2O$ , C. C. McDONNELL and C. M. SMITH (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2366-2369, fig. 1).—Continuing the study previously noted (E. S. R., 36, p. 313), it has been shown that the action of dilute ammonia on di-lead arsenate proceeds as follows: "Transposition to tri-lead orthoarsenate,  $Pb_3(AsO_4)_2$ , the supernatant solution remaining constant at the  $(NH_4)_2HASO_4$  stage until transformation is complete. Formation of solid solutions ranging from tri-lead arsenate to a basic arsenate, beyond which no further change occurs."

Yeast protein, C. NEUBERG (*Wechschr. Brau.*, 32 (1915), No. 38, pp. 317, 319, 320).—The author has isolated several samples of protein from yeast by heat coagulation of an aqueous extract of the dry material. An average sample was found to contain nitrogen 13.02 per cent, sulphur 0.92, and phosphorus 0.59.

The examination of the pure protein material showed the presence of alanin and tryptophan in the protein molecule, acids not reported by earlier investigators. The presence of the alanin suggested it as the source of acetaldehyde encountered in yeast fermentation, and this was verified by experiments carried out with the pure material.

The organic phosphoric acid of starch, J. H. NORTHPROP (*Diss., Columbia Univ.*, 1915, pp. 22).—This material has been essentially noted from another source (E. S. R., 34, p. 710).

Investigation on the occurrence of chitin and cellulose in bacteria, C. VAN WISSELINGH (*Pharm. Weekbl.*, 53 (1915), Nos. 33, pp. 1069-1078; 34 pp. 1102-1107).—From the results obtained it is concluded that chitin is not invariably present in bacteria, but often totally absent from the cell-wall material of the micro-organisms. The usual tests for the detection of chitin are deemed unsatisfactory.

The presence of cellulose was determined in *Bacterium xylinum*, but it is not considered to occur so commonly as indicated by many investigators.

The poisonous principle of poison oak (*Rhus diversiloba*), J. B. MCNAIR (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1417-1421).—The results of the investigation reported are summarized as follows:

The poisonous principle of poison oak (*R. diversiloba*) is not a glucosid of rhamnose, fisetin, and gallic acid. Syme's<sup>1</sup> work from which he concludes that the poison of poison ivy (*R. toxicodendron*) is a glucosid of fisetin, rhamnose,

---

<sup>1</sup> Some constituents of the poison ivy plant (*Rhus toxicodendron*). *Diss., Johns Hopkins Univ.*, 1906, pp. 37; *Amer. Chem. Jour.*, 36 (1906), No. 3, pp. 301-321.

and gallic acid should be repeated, because (1) it seems strange that two plants so closely related botanically should have such widely different poisons chemically; (2) all three of the so-called constituents of the poison are found in two nonpoisonous species of *Rhus*; (3) the natural glucosid of fisetin, rhamnose, and gallic acid is nontoxic; and (4) there is not sufficient evidence that the poisonous substance which Syme attempted to decompose was not a complex and containing a poisonous body in addition to one or more nontoxic glucosids.

**On the constituents of poison ivy (*Rhus toxicodendron*),** S. F. ACREE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1421-1425).—The author indicates and discusses the reasons for the variation in the results obtained by Syme and those reported in the above abstract. The botanical difference between the two plants investigated is considered to be the principal reason for the variation of the results.

**Lignoceric acid from rotten oak wood,** M. X. SULLIVAN (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 1027, 1028).—The author definitely isolated lignoceric acid from rotten oak wood. While no tests for cerebrosids in wood have been made, the presence of cerebronic acid in rotten wood is strongly indicated.

The experimental procedures are described in detail.

**Relation between the physical and chemical constants of oils and fats,** H. J. BACKER (*Chem. Weekbl.*, 13 (1916), No. 35, pp. 954-967).—The author discusses the relations that exist between the various constants and the molecular structure of oils and fats. Oils and fats poor in esters of saturated monocarboxylic acids exhibit a close relationship between the refractive index, density, saponification value, and iodine value. A formula for determining various constants from previously determined constants has been devised and is submitted.

Tabular data of the physical and chemical constants of a number of oils and fats are included.

**Storage changes in vegetable and animal oils,** H. A. GARDNER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 997, 998).—Detailed analytical data of the specific gravity, iodine number, saponification number, acid number, and refractive index of a number of oils obtained during various periods of storage, together with data on the effect of sterilization on these constants, are submitted.

**The fruit of *Smilax rotundifolia*,** CELIA ROGERS (*Chem. News*, 114 (1916), No. 2967, p. 172).—The fruit of the common greenbrier was examined and found to contain sugar to the extent of 7.5 per cent. The specific gravity of the oil extracted was found to be 0.8585, and it possessed a saponification value of 357.14. The ash was found to comprise 3.06 per cent of the dried fruit, and on analysis yielded the following percentage composition: Silica, 0.08; Fe<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>, 17.6; CaO, 0.79; MgO, 0.24; SO<sub>2</sub>, 7.92; Mn, 0.76; P<sub>2</sub>O<sub>5</sub>, 13.38; KCl, 32.38; NaCl, 5.28; and some carbon dioxide and unburned ash.

The nitrogen found was 1.12 per cent, which is equivalent to about 7 per cent of protein in the dried fruit. Citric and tartaric acids were shown to be present, but were not determined quantitatively.

**The fruit of *Vaccinium corymbosum*,** C. H. HARRIS and W. D. THRAMS (*Chem. News*, 114 (1916), No. 2960, p. 73).—The following percentage composition of the dried fruit of *V. corymbosum* (blueberry) is reported: Nitrogen, 0.7; oil, 0.93 (specific gravity at 18° C., 0.9, and saponification value 350.96); total sugar (identified as fructose), 41.46; and ash, 0.138.

On analysis the ash was found to have the following percentage composition: SiO<sub>2</sub>, 6.33; Al<sub>2</sub>O<sub>3</sub>, 17.39; Fe<sub>2</sub>O<sub>3</sub>, 10.5; CaO, 18.11; MgO, 11.48; K<sub>2</sub>O, 5.65; Na<sub>2</sub>O, 2.26; SO<sub>2</sub>, 10.94; P<sub>2</sub>O<sub>5</sub>, 14.36; MnO, 0.35; and a little undetermined carbon dioxide.

Tartaric and a trace of citric acid were also determined in the aqueous and alcoholic extracts.

The cause of the ureolytic action of soy beans, D. H. WESTER (*Chem. Weekbl.*, 13 (1916), No. 24, pp. 663-677).—From the results of the study the author concludes that the ureolytic action of soy beans is not due to bacterial action. The activity of an aqueous glycerin extract was not hindered by antiseptics, except mercuric chlorid and formaldehyde. An aqueous glycerin extract easily passed through a Chamberland-Pasteur candle, the filtrate being practically inactive. This inactivity is not attributed to the removal of any microorganisms, but as probably due to the absorption of the colloidal enzymic material as indicated by the complete loss of the ureolytic action of an extract by treatment with kaolin. The action of sunlight on the extract retarded the enzymic action considerably. Normally the action of the enzym was found to be complete in eight hours at room temperature, in three hours at 30° C., and in two hours at 50°.

On account of the high fat content of the soy beans the author considers it advantageous to remove the oil before preparing the aqueous glycerin extract, as it facilitates later filtration of the extract. In the determination of urease in urine the presence of glucose was found not to interfere up to concentrations of 3 per cent.

An aqueous glycerin extract of soy beans was found to be the most suitable form in which to use the enzym, it retaining its activity for about three months. The enzym in the bean, however, was found to be active after three years.

See also previous notes by Groll (*E. S. R.*, 35, p. 110) and Mom (*E. S. R.*, 35, p. 112).

The separation of oxidase reactions from the catalase reaction, G. B. REED (*Bot. Gaz.*, 62 (1916), No. 4, pp. 303-310 figs. 3).—Experiments are reported in which platinized electrodes subjected to either nascent oxygen or hydrogen, as previously described (*E. S. R.*, 35, p. 713), were used.

The results indicate that "factors which have no effect on the peroxidase activity do alter the catalase action. In other words, the peroxidase action is quite independent of the rate of hydrogen peroxid decomposition, and the two reactions may be regarded as quite separate."

Experiments showing that a similar separation of the oxidase from the catalase may occur in the living cell are to be discussed in a subsequent paper.

The relation of oxidase reactions to changes in hydrogen ion concentration, G. B. REED (*Jour. Biol. Chem.*, 27 (1916), No. 2, pp. 299-302).—Experiments are reported which indicate that 0.0005-0.007 molar hydrochloric acid is sufficient to prevent the action of certain oxidases. The optimum activity of the oxidases appears to be reached when they are in a medium which is very nearly neutral or slightly alkaline.

Studies in the measurement of the electrical conductivity of solutions at different frequencies.—V. Investigations on the use of the Vreeland oscillator and other sources of current for conductivity measurements. VI. Investigations on bridge methods, resistances, cells, capacities, inductances, phase relations, precision of measurements, and a comparison of the resistances obtained by the use of inductance and capacity bridges. VII. Investigations on the true and apparent resistances, voltage, apparent capacity, size and character of electrodes, ratio of inductance changes to resistance changes, and the relation of induction and capacity to frequency, W. A. TAYLOR and S. F. ACREE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2396-2430, figs. 19).

The effect of pressure upon the potential of the hydrogen electrode, N. E. LOOMIS and S. F. ACREE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2391-2396).

**Review: The preparation of conductivity water, J. KENDALL** (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2460-2466).—The literature on the preparation of conductivity water is reviewed.

By one distillation in the open air of tap water to which a few cubic centimeters of Nessler's solution had been added a water of specific conductivity  $0.9 \times 10^{-6}$  at 25° C. was obtained. By redistillation in silica vessels and collecting the distillate hot, water of specific conductivity  $0.2-0.6 \times 10^{-6}$  at 25° was obtained. Such low values, however, were only observed when the distillate was tested at once. On standing, the values rose to  $0.8-0.9 \times 10^{-6}$  and remained stationary for some time. The specific conductivity of the water thus obtained is the same as that given by a saturated solution of carbonic acid under atmospheric conditions.

It is indicated that a water obtained as described, to which a proper correction is applied, is as satisfactory in conductivity work as waters distilled by a more elaborate method.

**A simple mercury sealed ether still, O. C. SMITH and D. G. MORGAN** (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, p. 1039, fig. 1).—A convenient arrangement for the distillation of ether, constructed at the Oklahoma Experiment Station, is described and illustrated by drawings.

**An electrically heated vacuum desiccator, T. B. ROBERTSON and C. L. A. SCHMIDT** (*Jour. Biol. Chem.*, 27 (1916), No. 2, pp. 429-431, fig. 1).—A vacuum desiccator, which readily accommodates a 9 in. filter, and its manipulation are described. The desired temperature in the evacuated chamber is maintained by the heated vapor of dichloromethane or some other suitable compound having a boiling point within the range of the temperature desired.

**Analysis by machinery, E. SINKINSON** (*Chem. News*, 114 (1916), No. 2967, pp. 170-172, figs. 3).—The author describes in detail an electrically operated apparatus for washing precipitates which is considered to be a great time saver. The device is simple in construction, has few moving parts, and can be manipulated with comparatively little attention.

**A method for the determination of nitric nitrogen, F. M. SCALES** (*Jour. Biol. Chem.*, 27 (1916), No. 2, pp. 327-337, fig. 1).—A new method for the determination of nitric nitrogen in which a zinc-copper couple is used is described in detail. The couple used will reduce a nitrate solution at the boiling point, the reduction thus proceeding during the distillation. Soil solutions high in organic matter yield accurate results if clarified with alumina cream. Owing to the very slight alkalinity of the reducing solution unstable organic compounds are not destroyed in the procedure.

Experimental data indicating the accuracy of the method are submitted. A simple apparatus which yields excellent results with the method has been devised and is described.

**The efficiency of the aeration method for distilling ammonia; in answer to certain criticisms, P. A. KOBER** (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2568-2572).—Contrary to the results reported by Falk and Sugiura (E. S. R., 35, p. 110) and others the author maintains that the distillation of ammonia by aeration yields accurate results. To insure accurate results, however, it is necessary to use a sufficient volume of air, as high a column of liquid with as low a volume as is convenient, and an adequate excess of a saturated solution of pure sodium hydroxid. Impure alkali containing or producing sulphite introduces an error. Potassium hydroxid should not be used because the difficultly soluble potassium sulphate which separates may carry down ammonia by occlusion or as a double salt.

It is indicated that the complete removal of ammonia should be tested with Nessler's solution, and that the aeration should be run slowly or at half speed for the first minute or two.

The separation of lithium from the other alkali metals, S. PALKIN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2326-2332).—After some preliminary experimentation the author devised a modified procedure, the essentials of which are as follows:

The dried mixed chlorids are dissolved in a definite minimum amount of water, acidified with hydrochloric acid, and the major portion of the sodium and potassium chlorids precipitated by the addition of absolute alcohol followed by ether. The precipitated chlorids are filtered, the filtrate evaporated, the residue taken up in absolute alcohol containing a drop of hydrochloric acid, and the residual amount of sodium and potassium chlorids, which is usually very small, is completely precipitated by the addition of ether. These chlorids are then filtered through the same crucible as used for the first precipitate and the residue washed with ether-alcohol mixture. The ether-alcohol solution of lithium is evaporated on the steam bath, the residue taken up with a little water, and a slight excess of sulphuric acid added. The solution is then transferred to a weighed porcelain or platinum dish, evaporated to dryness, and the residue gently ignited.

The following optional method is also described:

The ether-alcohol solution of the lithium is evaporated to dryness in the steam bath and finally dried in an oven at 110° C. for from 15 to 20 minutes. The residue is taken up in from 5 to 10 cc. of alcohol, warmed if necessary, and then diluted with about 50 cc. of water. If a slight sediment remains the liquid is filtered through a Gooch crucible and washed with water, a few drops of phenolphthalein are added to the filtrate, and the liquid titrated with tenth-normal alkali. The chlorids are precipitated as the silver salt and from the weight of the latter is subtracted the amount corresponding to the hydrochloric acid determined in the titration.

Method of extraction as affecting the determination of phosphoric acid in soils, H. HALE and W. L. HARTLEY (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 1028, 1029).—Analytical data submitted show that the 2-hour digestion with twice-normal nitric acid, as described by Brauer (*E. S. R.*, 33, p. 110), extracts as much phosphoric acid as the official 10-hour digestion with hydrochloric acid of specific gravity 1.115 (*E. S. R.*, 20, p. 512).

Investigation of methods for the determination of the soil reaction, H. R. CHRISTENSEN (*Tidsskr. Planteavl.*, 23 (1916), No. 1, pp. 1-83, figs. 4).—Various qualitative and quantitative methods for determining the reaction of soils have been investigated.

The results indicate that a distinction between the true acidity and the base absorption area of the soil must be made. The method of Hopkins, given in Bulletin 73 of the Division of Chemistry (*E. S. R.*, 14, p. 1045), and that of Daikuhara (*E. S. R.*, 31, p. 618), were found to yield reliable results in the determination of soil acidity. The procedure of Baumann and Gully (*E. S. R.*, 19, p. 1008) was found to yield more accurate results than that of Tacke and Stüchting (*E. S. R.*, 19, p. 1009).

No free acids were found in sphagnum turf. The use of litmus paper for the qualitative determination of soil acidity is deemed unreliable.

The difficulty of determining the true acidity of a calcareous soil is indicated and briefly discussed.

A bibliography of 33 references is included.

The determination of volatile fatty acids according to the method of Duclaux, A. VOITKEVICH (A. WOJTKIEWICZ) (*Viēstnik Bakt. Agron. Sta. V. K. Ferrein*, No. 21 (1914), pp. 180-188).—The method is described in detail, and analytical data obtained by its application to a mixture of acetic, propionic, and butyric acids submitted.

In a comparative study of the method and the distillation of pure acids results not differing more than 5 per cent from each other were obtained. The variation is attributed to differences in the conditions of the distillations. The method is deemed to yield accurate and trustworthy results.

Estimation of sugar in meat products, particularly extracts, W. B. SMITH (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 1024-1027).—Slightly modified methods in which mercuric acetate and picric acid are used as protein precipitants are outlined.

The experimental data submitted show that the clarification of meat extract solutions for the estimation of sugar by Fehling's solution is best accomplished by using an excess of picric and phosphotungstic acids, followed by a very small quantity of hydrochloric acid. With the proper precautions reducing sugar may be determined within 0.1 or 0.2 per cent in the presence of sucrose. The total reducing sugar may be determined within 0.1 per cent.

The determination and distribution of moisture in bread, HANNAH L. WESSLING (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 1021, 1022, figs. 2).—For the determination of moisture in bread the author uses one-half or one-fourth of a loaf, depending upon the character of the crust, and then proceeds as follows:

A suitable portion of the bread is weighed as quickly as possible in a tared dish on a torsion balance, and then carefully heated at a temperature not exceeding 60° C. until practically dry. The dry bread is allowed to stand exposed at room temperature for a few hours in order that its moisture content may come into equilibrium with that of the air, and the loss in moisture to this point is then determined. The air-dried sample is immediately ground to a fine meal and the moisture determined in a 2-gm. sample in the vacuum oven at the temperature of boiling water. From the percentage of moisture obtained in this subsample the total percentage of moisture in the bread is calculated by adding this to the amount lost on heating at 60°. This procedure is practically the same as that previously described.<sup>1</sup>

The results obtained indicate that there is no appreciable difference in moisture content in slices of bread taken at a reasonable distance from the end of the loaf, or in the crumb of any individual slice taken at a reasonable distance from the crust. A great difference, however, was observed between the moisture obtained in the whole bread (as determined on one-half or one-fourth of a loaf) and that in either the crust or crumb taken separately or in one entire slice. In reporting the moisture content of bread it is necessary, therefore, to state what portion of the bread was used as well as how the moisture was determined.

Microscopical examination of chocolates and cocoas.—Determination of shell material in seeds, E. COLLIN and L. GOBERT (*Ann. Falsif.*, 9 (1916), No. 92-93, pp. 191-202, figs. 8).—The authors discuss the materials present in chocolate and cocoa which might be considered as adulterants and outline in detail a procedure for microscopical examination. Formulas for calculating the quantity of such foreign material are submitted, together with analytical data obtained from the examination of six samples of chocolate and seven of cocoa. Since the presence of such material can hardly be avoided or prevented in the finished product, it is suggested that in order to secure uniformity the

<sup>1</sup>Arb. K. Gsndhtsam., 48 (1915), No. 4, pp. 605, 606.

quantity of extraneous material should be controlled by a simple method of examination.

The determination of gum in gum sirups, E. LUCE (*Ann. Falsif.*, 9 (1916), No. 92-93, pp. 227-231).—The author briefly describes and comments on the methods of Roussin, Bellier (E. S. R., 25, p. 109), and Rocques and Sellier (E. S. R., 28, p. 206). Analytical results obtained show that either the procedure of Rocques and Sellier or that of Bellier is of practical value, the former being slightly the more accurate. The presence of dextrin causes high results. This, however, is a valuable indication of adulteration and a cause for the rejection of the material as nonofficial.

The polariscopic examination of gum sirups before and after inversion is deemed to be an excellent and accurate procedure.

A new method for the determination of vanillin in vanilla extract, A. W. DOX and G. P. PLAISANCE (*Amer. Jour. Pharm.*, 88 (1916), No. 11, pp. 481-484).—The authors at the Iowa Experiment Station describe the following gravimetric procedure based on the reaction of thiobarbituric acid and certain aromatic aldehydes previously noted (E. S. R., 36, p. 318) for the determination of vanillin:

Twenty-five cc. of the extract is dealcoholized in the usual manner, transferred to a 50-cc. standard sugar flask, and filled to the mark with lead acetate solution. After standing for several hours at about 37° C. the contents of the flask are filtered through a dry filter, 40 cc. of this filtrate is transferred to another 50-cc. flask, and sufficient hydrochloric acid added to bring the volume to 50 cc. and the acidity to 12 per cent. After standing for a few minutes the lead chlorid is filtered off and 40 cc. of the filtrate taken for the determination. Thiobarbituric acid in 12 per cent hydrochloric-acid solution is added, and an orange-colored precipitate results. The precipitate is allowed to stand overnight, filtered on a Gooch crucible, washed with hydrochloric acid, and dried at 98°. A simple correction for slight solubility is necessary. Analytical data submitted indicate the accuracy of the procedure.

The method is not applicable, however, to extracts which contain caramel, since the caramel contains furfural derivatives which react with thiobarbituric acid. When caramel is present the filtrate after clarification is brown instead of straw colored. A very delicate test was devised by the authors in which after clarifying and removing the excess of lead as chlorid, phloroglucinol is added. In the presence of caramel a brown precipitate is formed, and in its absence the vanillin gives a delicate rose pink color or slight pink precipitate.

The use of amyl alcohol in Gerber's method for the determination of fat in milk, ORLA-JENSEN (*Mælkeritid.*, 29 (1916), No. 7, pp. 104-106).—From a comparison of the Babcock and Gerber methods it is indicated that the latter in general yields the higher results, the error increasing with the percentage of fat in the milk. The necessity of using amyl alcohol of standard purity is emphasized.

The biological method for judging the freshness of milk according to Parashchuk (Paraschtschuk), P. KALANTAROV (*Vêstnik Bakt. Agron. Sta. V. K. Ferrein*, No. 21 (1914), pp. 84-98).—The author investigated the method previously noted (E. S. R., 31, p. 506), and found that all the strains of lactic acid bacteria will grow well in the three grades of milk, very fresh, fresh, and old. No evidence of any difference in action in the sense indicated by the originator of the method was noted.

Other experiments were carried on with various combinations of the micro-organisms recommended in the original procedure, with the same negative results.

It is concluded that the method is absolutely impracticable and unreliable.

A polariscopic determination of sugar in "condensed milk," R. O. BROOKS (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, 1022-1024).—The following modified procedure is described:

Fifty gm. of the well-mixed sample is diluted with water to exactly 100 cc. and carefully shaken until completely dissolved. Exactly 26 cc. (13 gm.) is pipetted into a beaker, diluted with water to about 40 cc., and Fehling's solution added drop by drop with constant stirring until the proteins and fat are precipitated. Usually about 1.5 cc. is sufficient. The mixture is then filtered and the precipitate washed with water until the filtrate measures exactly 100 cc. The filtrate is thoroughly mixed and a direct reading taken in a 200 mm. tube of the polariscope at a temperature between 20 and 30° C. To exactly 50 cc. of the filtrate 5 cc. concentrated hydrochloric acid is added, mixed, and allowed to stand overnight at a temperature between 20 and 30°. The acid is exactly neutralized with strong alkali, using phenolphthalein, and again very slightly acidified with hydrochloric acid. It is then made up to 100 cc., filtered, and the invert reading taken in a 200 mm. tube, as above. The direct reading is multiplied by 2 and the invert reading by 4, and the sucrose calculated by Clerget's formula, using the factor 141.7 as follows:

$$\text{Sucrose} = \frac{100 (\text{Direct reading} - \text{Invert reading})}{141.7 - \frac{\text{Temp.}}{2}}$$

The procedure described is considered to be rapid and to yield accurate results.

A study of proteins in urine and a comparison of gravimetric and nephelometric methods for their estimation, J. T. W. MARSHALL, H. W. BANKS, 3RD, and S. S. GRAVES (*Arch. Int. Med.*, 18 (1916), No. 2, pp. 250-262).—A nephelometric method, using egg albumin as a standard for the determination of protein in urine, and a formulative expression of the relation between the light and concentration are submitted.

It is concluded that "the nephelometric method is satisfactory for clinical purposes, and that the results are in fair agreement with those obtained by the gravimetric method. For urines of low protein concentration the method is no doubt more accurate than the gravimetric. . . ."

"The nitrogen content of the protein recovered has been found to be lower than the generally accepted values in the case of urine protein."

An accurate aeration method for the determination of alcohol in fermentation mixtures, A. W. DOX and A. R. LAMB (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 11, pp. 2561-2568).—The determination of alcohol by oxidation with sulphuric acid and dichromate solution has been carefully studied. The best results were obtained when the alcohol was determined by distillation and titration of the acetic acid formed.

A procedure in which the solution is saturated with ammonium sulphate and the alcohol carried over into concentrated sulphuric acid by a current of air is described. The alcoholic sulphuric acid solution is then mixed with a solution of potassium dichromate, and the acetic acid distilled off at once. The method has been used for the determination of alcohol in various kinds of silage at the Iowa Experiment Station with very satisfactory results.

The precautions necessary in the presence of interfering substances are discussed.

The distillation of cane sugar at the distillery of Oisemont (Somme), É. SAILLARD (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 24, pp. 676-681).—These pages briefly record the results of the use of molasses, beets, and apples

as sources of alcohol; the preparation of fermentation mixtures; and yields of the finished product. A list of the apparatus used in the work is included.

**Home and farm canning**, W. V. CRUESS (*California Sta. Circ.* 158 (1916), pp. 31, figs. 10).—This discusses the subject under the general topics of causes of spoiling; various methods of sterilization; general principles of home canning; and operations, materials, and equipment necessary in canning. Special directions for canning various fruits and vegetables are given in some detail.

**The theory and practice of the use of pure yeast in the preparation of fruit wines**, S. A. KOROLEV (*Věstnik Bakt. Agron. Sta. V. K. Ferrein*, No. 21 (1914), pp. 99–152).—The literature on the subject is reviewed in some detail and a bibliography of 41 references included.

**Note on the Burma myrobalans or "panga" fruits as a tanning material**, PURAN SINGH (*[Indian] Forest Bul.* 32 (1916), pp. 5).—Experimental data submitted show that Burma myrobalans are inferior to the Indian myrobalans in tanning strength, in color, and in containing an excess of nontannin material. It is indicated, however, that they can be used satisfactorily for tanning, especially when mixed with other materials similar to the Indian myrobalans. A procedure for the preparation of Burma myrobalans for the trade is outlined.

**The conservation of pork, with special reference to preservation by boxing and tubbing**, E. KALLERT and R. STANDFUSS (*Zent. Einkaufsgesell. Beschränkt. Haftung, Abhandl. No. 4* (1916), *Orig.*, pp. 96, figs. 2).—This pamphlet discusses the preservation of pork by salting, pickling, and smoking, and various experiences in conserving by boxing and tubbing. An appendix containing brief directions for the various procedures of conserving pork, rules to be conformed with in the conservation, and certain control measures in the inspection of such products is included.

**Conservation of fish by freezing**, R. PLANK, E. EHRENBAUM, and K. REUTER (*Zent. Einkaufsgesell. Beschränkt. Haftung, Abhandl. No. 5* (1916), *Orig.*, pp. 248, pls. 9, figs. 37).—This publication is divided into two parts, a comparative investigation of different procedures of freezing, and histological and taste changes in frozen fish.

In general it is concluded that the rapid freezing in salt solution is to be highly recommended. Direct freezing in ice was also found to yield excellent results for certain fish. Slow freezing in cold air, however, was not found to be satisfactory. With proper care during the preserving period, there is only a very slight change in the taste of the fish. Thawing by soaking in cold water was found to be the most economical and satisfactory procedure.

**A method for determining the strength of paper when wet**, E. O. REED (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 11, pp. 1003, 1004).

## METEOROLOGY.

**The weather map: An introduction to modern meteorology**, N. SHAW (*London: Meteorological Office*, 1916, pp. 94, pls. 8, figs. 20; *rev. in Nature [London]*, 98 (1916), No. 2459, pp. 286, 287).—This is a short elementary treatise which appears to be designed primarily for the benefit of those who are making use of meteorology in the present war, but deals with the subject in such a way as to be of interest to others. The lessons of the weather maps are especially well presented.

**Highest and lowest temperatures of 1916** (*U. S. Dept. Agr., Nat. Weather and Crop Bul.* 32 (1916), p. 2, pl. 1).—Two charts showing the extremes of temperatures during the year are given and briefly explained.

As compared with 1915 "the temperatures were considerably lower in 1916 in Montana, Wyoming, Colorado, Kansas, and eastern Washington. The

isotherms of 10 and 20° were farther south in the cotton belt in 1916 than in 1915, as were also the lines of 32 and 40° in Florida."

**Frosts of 1916** (*U. S. Dept. Agr., Nat. Weather and Crop Bul. 31 (1916), p. 2, pl. 1*).—Two charts showing dates of occurrence of the last killing frost in spring and the first in autumn are given and briefly discussed.

The last killing frost in spring occurred at an earlier date than the average in Texas, eastern Arkansas, southern Tennessee, the upper Mississippi Valley, States immediately north of the Ohio River, and the Middle and North Atlantic States. It was later than usual in South Carolina, Georgia, and northeastern Florida. "In most portions of the Atlantic States north of Georgia and generally in the States around Lake Michigan killing frosts during the present autumn occurred at a later date than the average; but in most of the central Gulf States and Texas, and generally in the Great Valley of California, killing frost occurred somewhat earlier than usual."

**Report of the meteorological service [of Canada], R. F. STUPART** (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), App. C, pp. LXXXIII-CI*).—This is a summary account of the work of the service in the physics branch, agricultural meteorology, terrestrial magnetism, and seismology during 1916, with a record of phenological observations in the different Provinces of Canada during 1915.

**The meteorological office of Argentina, G. G. DAVIS** (*Min. Agr. Argentina, Mem. Cong. Nac., 1914-15 pp. 251-324*).—This article briefly reviews the history of this office, which is a bureau of the ministry of agriculture of Argentina, and gives its status at the end of 1915, special attention being given to the subject of hydrometric and magnetic observations. It contains a complete list of stations and observers, showing that at the end of 1915 there were 42 stations of the first class, 156 of the second, 12 of the third, and 1,930 of the fourth, making a total of 2,140 stations of all classes.

**The climate of France, G. BIGOURDAN** (*Le Climat de la France. Paris: Gauthier-Villars & Co., 1916, pp. 135, figs. 61; rev. in Rev. Gén. Sci., 27 (1916), No. 22, pp. 663, 664*).—This book, based upon the work of the Central Meteorological Bureau of France, shows the mean values and daily, monthly, and annual variations, as well as the extremes of the principal meteorological elements—temperature, pressure, and wind—for each place in France where observations have been taken.

**The oscillation of climate in southeast Russia, A. TOL'SKĪ (A. TOLSKY)** (*Zhur. Opytn. Agron. (Jour. Agr. Expt.) 17 (1916), No. 4, pp. 255-277, figs. 2*).—A certain periodicity of dry and hot and moist and temperate seasons in this region during the nineteenth century is noted and discussed.

**Influence of the weather on the use by plants of fertilizers, H. R. CHRISTENSEN** (*Tidsskr. Plantavl, 23 (1916), No. 2, pp. 251-288*).—Experiments showed that the meteorological conditions of the year influenced greatly the absorption of fertilizers by plants. The absorption of mineral fertilizers, such as sodium nitrate alone or in addition to manure, was less the more favorable the meteorological conditions were for plant growth, indicating that in years when the weather conditions were such as to increase the absorption of the nutritive substances of manure, the plants needed less the nutritive substances contained in the mineral fertilizers.

## SOILS—FERTILIZERS.

**Measurements of soil fertility, W. H. JORDAN** (*New York State Sta. Bul. 424 (1916), pp. 389-412*).—This bulletin reports the results of chemical analyses and vegetation tests of nine unlike soils brought to the station from different parts

of the State for the purpose of studying the relation of different methods of chemical examination to crop-producing power.

"The soils were submitted to chemical examination by different methods: (1) Complete analysis; (2) a determination of the material soluble in hydrochloric acid of the specific gravity of 1.115 by the A. O. A. C. method; (3) a determination of the materials rendered soluble by continued leaching for 10 days with water, N/200 HCl and N/25 HCl; [and] (4) a determination of the soluble material obtained by shaking five hours with water, N/200 HCl, and N/25 HCl.

"These soils showed by the vegetation tests greatly unlike crop-producing capacity, the dry matter produced varying in two years from 161.5 gm. per box to 9.4 gm. per box. By no one of the methods of chemical examination was there established any relation between the amounts of nitrogen, phosphoric acid, and potash, either total or soluble, and crop-producing capacity. There appeared to be some relation between the total soluble matter in the soil and productiveness, to the extent that the two soils giving a very low yield of barley showed greatly less solubility than did the others. This relation, however, was not consistent throughout." The general conclusion reached was that the laboratory methods so far devised are not capable of measuring the fertility of soils.

Concerning tillage, R. T. BURDICK (*Vermont Sta. Bul. 198 (1916), pp. 50-83, figs. 19*).—This article deals with the principles and practice of tillage. Twenty-three references to literature cited are included.

Soil survey of Clay County, Alabama, A. E. TAYLOR, E. S. VANATTA, N. E. BELL, and J. L. ANDRESS (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 41, fig. 1, map 1*).—This survey, made in cooperation with the State of Alabama, and issued December 30, 1916, deals with the soils of an area of 385,280 acres in the Piedmont Plateau and Appalachian Mountain provinces in east-central Alabama. "The topography is undulating to mountainous, and consists largely of parallel ridges and valleys, with broad rolling areas. . . . There are no large streams, but all parts of the county are reached by drainage ways. . . ."

"About 96 per cent of the soil is residual in origin, about 3 per cent alluvial, and about 1 per cent colluvial. The loam and stony loam types of soil predominate." Including rough stony land, 23 soil types of 12 series are mapped, of which the Louisa loam and stony loam and the Talladega and Louisa slate loams cover 18, 17, 11.7, and 8.3 per cent of the area, respectively. The Louisa series is the most extensive, covering about 56 per cent of the area.

Soil survey of Clinton County, New York, E. T. MAXON and W. R. CONE (*N. Y. State Col. Agr., Cornell Univ. Ext. Bul. 3 (1916), pp. 30-65, pl. 1, fig. 1*).—This survey has been previously noted from another source (*E. S. R., 35, p. 18*).

The soils of Cuba, J. T. CRAWLEY (*Estac. Expt. Agron. Cuba Bol. 23 (1916), pp. 86, pls. 19*).—This bulletin discusses in some detail the more important physical, chemical, and biological factors of soils, and reports the results of chemical analyses of about 305 samples of typical Cuban soils and chemical analyses of about 28 samples of Cuban waters.

Microbiological investigation of the soil in connection with crop yields, A. VOITKEVICH (A. WOJTKIEWICZ) (*Věstník Bakt. Agron. Sta. V. K. Ferrein, No. 21 (1914), pp. 153-179*).—Studies in all four seasons of the year of bacterial numbers, nitrogen-fixing power, nitrification, denitrification, putrefaction, urea decomposition, and carbon dioxide production in certain fallow soils and soils planted to winter crops, root crops, clover, and oats are reported.

The bacterial numbers were greatest in the spring and were only slightly higher in summer than in winter. No striking differences in bacterial numbers

with the time of year were noted. The nitrogen-fixing power was lowest in winter and gradually increased through the spring and summer to a maximum in the fall.

On the basis of these results the author judges these soils to be entirely unsatisfactory with reference to productivity.

It was further found that the greatest bacterial numbers and nitrogen fixation occurred in a soil growing root crops, while the fallow soil stood nearly the last in both. Conclusions based on these results are considered unsafe.

**The organic matter of the soil.—I, Some data on humus, humus carbon, and humus nitrogen, R. A. GORTNER (*Soil Sci.*, 2 (1916), No. 5, pp. 395-442, pls. 2, figs. 17).**—Experiments conducted at the Minnesota Experiment Station are reported in which “eight mineral soils, three peats, one muck, and five samples of unchanged vegetable materials were selected and analyzed for total carbon and total nitrogen; for carbon and ‘humus’ soluble in 4 per cent  $\text{NH}_4\text{OH}$  both before and after leaching the substances with 1 per cent  $\text{HCl}$ ; for carbon and nitrogen soluble in 4 per cent  $\text{NaOH}$  both before and after leaching the material with 1 per cent  $\text{HCl}$ ; for carbon and nitrogen extracted by 4 per cent  $\text{NaOH}$  from the residue remaining after the soil or vegetable materials which, without previous treatment, had been extracted with 4 per cent  $\text{NaOH}$  and subsequently leached with acid; for carbon and nitrogen extracted by the addition of water to the residue remaining from the preceding extraction; and for nitrogen in the 1 per cent  $\text{HCl}$  extract. Colorimetric measurements were also made on the various solutions.”

The results of a comparison of the data obtained are taken to indicate that “the ‘humus’ extract of soils and peats is not a typical soil product, formed in the soil by the action of bacteria and fungi, for very similar extracts can be obtained from unchanged vegetable materials. ‘Humus’ does not consist entirely of a black compound, or compounds, but it also contains a large proportion of almost colorless substances, the presence of which is normally masked by the black color. A 4 per cent solution of sodium hydroxid does not extract either the same substances or the same quantity of substances as does a 4 per cent solution of ammonium hydroxid. From a given soil, after leaching with 1 per cent  $\text{HCl}$ , ammonium hydroxid will extract less carbon and at the same time more color than will a sodium hydroxid solution. In general the forms of soil nitrogen appear to be quite similar in solubility to those forms occurring in unchanged vegetable materials, the only noteworthy difference being that vegetable materials contain a very considerable amount of nitrogen soluble in 1 per cent  $\text{HCl}$  while soils contain only a small quantity, and the soils contain an appreciable amount of nitrogen quite insoluble in 4 per cent  $\text{NaOH}$ , in decided contrast to the unchanged vegetable materials.”

All the mineral soils and the one calcareous peat tested contained a soil pigment which was absent from the unchanged vegetable materials or the acid peats, was intensely black, and contained only a relatively small proportion of the soil nitrogen.

From the results obtained, it is considered extremely doubtful if a specific “humification” of plant materials takes place in the soil.

It is concluded that “the common practice of comparing ‘humus nitrogen,’ determined in a 4 per cent  $\text{NaOH}$  extract, with ‘humus,’ obtained by 4 per cent  $\text{NH}_4\text{OH}$ , can give only meaningless results. . . . A determination of the ‘humus’ as ordinarily carried out appears to be wholly without scientific justification. The European method of reporting ‘humus’ by making a determination of total organic carbon appears to be far preferable.”

Thirty-one references to literature bearing on the subject are cited.

Chemical, bacteriological, and agricultural investigations on an experimental cultivated soil, K. DIEM (*Meded. Deli-Proefstat. Medan*, 9 (1916), No. 5, pp. 143-176, pls. 7).—Experiments on the influence of methods of cultivation, of physical, mechanical, and chemical properties of tobacco soils, and of mixing the ashes of weeds with soils on the height and green weight of tobacco plants are reported.

No relation was found to exist between the green weight or height of plant and the soil properties. The intermixing of considerable amounts of weed ashes with the soil also had no appreciable influence on the stand of tobacco.

Influence of pine resin and tannin on the nitrogen economy and on the physical properties of the soil, A. KOCH and ALICE OELSNER (*Centbl. Bakt. [etc.]*, 2. Abt., 45 (1916), No. 1-5, pp. 107-118; *abs. in Jour. Chem. Soc. [London]*, 110 (1916), No. 644, I, p. 454).—The results of experiments on the influence of colophony on the biological transformation of nitrates are taken to indicate that pine resin in soils produces a source of energy for nitrate-reducing soil bacteria. This is thought to explain in part why soils containing resin contain less nitrate than soils containing no resin. It is further considered possible that nitrification in soils is hindered by the presence of resin constituents dissolved by alkali salts.

In experiments on the influence of tannin on the biological transformation of soil nitrates, it was found that tannin is readily assimilated by mold fungi. The results are taken to indicate that the increased growth of fungi gives rise to a temporary loss of nitrogen present as nitrate and ammonia, thus explaining why soils containing tannin contain only small amounts of nitrate. With reference to the production from tannin of poisonous substances inhibiting nitrification it was found that no oxalic acid was produced from tannin by *Aspergillus niger*.

The addition of tannin to soils resulted in the production of a dark color not due to iron, and increased the power of retaining water. Large additions of tannin caused the soil to become hard, this being attributed tentatively to the precipitation of colloids.

Influence of moisture on the nitrogen changes in soils, A. E. TRAAEN (*Centbl. Bakt. [etc.]*, 2. Abt., 45 (1916), No. 1-5, pp. 119-135; *abs. in Chem. Abs.*, 10 (1916), No. 16, p. 2118).—Experiments on nitrification, denitrification, and nitrogen fixation showed that nitrogen fixation especially was most active when the soil contained medium amounts of moisture.

On the nature of ammonification and nitrification, K. MIYAKE (*Soil Sci.*, 2 (1916), No. 5, pp. 481-492, fig. 1).—A mathematical analysis, made at the Tohoku Imperial University, Japan, of the processes of ammonification and nitrification in soils as described in experimental work by others is reported. On the basis that the processes of ammonification and nitrification are autocatalytic chemical reactions, it is pointed out that in these processes the maximum increase of ammonia and nitric acid in a unit of time occurs when the total amount of production due to these processes is half completed.

"Increases of ammonia and nitric acid in the processes are in accordance

with the formula:  $\text{Log} \frac{x}{A-x} = K(t-t_1)$ , where  $x$  is the amount of am-

monia and nitric acid which has been produced at time  $t$ ,  $A$  is the total amount of ammonia and nitric acid produced during the process,  $K$  is a constant and  $t_1$  is the time at which half of the total amount of ammonia and nitric acid is produced."

The gain in nitrogen from the growth of legumes on acid soils, E. B. FRED and E. J. GRAUL (*Wisconsin Sta. Research Bul. 39 (1916), pp. 42, figs. 20*).—This is a progress report of pot and field experiments made to study the growth and nitrogen-fixing power of red clover, alfalfa, and soy beans in acid Colby silt loam and acid Plainfield sand under the influence of liming and inoculation and to study the nitrogen balance in an acid soil before and after growing a leguminous crop.

It was found that inoculation and liming produced striking increases in plant growth, half enough lime to neutralize the soil acidity being sufficient for the production of good crops. "The growth and nitrogen content of alfalfa plants on Colby silt loam soil are greatly increased by inoculation. This influence was most noticeable in the limed series. The benefit of lime alone was much less pronounced than inoculation alone. In the case of soy beans in the same soil, inoculation caused a very marked increase in both yield and quantity of nitrogen. Lime apparently did not have any decided influence on soy beans." In the Plainfield sand an enormous increase of nitrogen in the plant was noted from inoculation, especially after the second cutting.

Clover on Colby silt loam responded only slightly to liming and not at all to inoculation, but on Plainfield sand responded readily to both inoculation and liming. The results obtained from field experiments with alfalfa and soy beans on Colby silt loam agreed in general with those of the pot tests.

Two fundamental facts are brought out, (1) that the characteristic effect of inoculation of alfalfa on acid Colby silt loam and acid Plainfield sand is an increase in plant growth and in the fixation of atmospheric nitrogen, and (2) that small applications of lime on acid soils are more economical than large applications.

Twenty-one references to literature bearing on the subject are appended.

The physiologically acid and alkaline salts and their importance in the explanation of soil sickness, J. H. ABERSON (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch. [Wageningen], 11 (1916), No. 1-3, pp. 1-128, pls. 10*).—The work of others bearing on the subject is reviewed, and experiments are reported from which the following conclusions are drawn:

The physiologically acid and alkaline salts exert very little influence on soil reaction in the field, although much of the lime is lost from soil by heavy fertilization with ammonium salts, thus causing marked changes in the soil properties. Changes of soil reaction in pot cultures can be considered as representing field conditions in only a very general way. The alkaline or acid reaction of the soil is not the cause of the so-called dry spot sickness (*Dürrfleckenheit*).

It is stated that the dry spot sickness appears on all soils, but when ammonium sulphate is used the disease has a different appearance than the so-called acid sickness attributed to the slow formation of nitrites. The disease was found to accompany the occurrence of nitrites in soils and *Bacillus nitrosus* was obtained in pure culture. Injurious action took place only where nitrification was slow and insufficient, and treatment producing active nitrification eradicated the trouble.

The vertical distribution of phosphorus in the surface soil of prairies, F. J. ALWAY and C. O. ROST (*Soil Sci., 2 (1916), No. 5, pp. 493-497*).—Determinations of the phosphorus content of each inch section of the surface foot of the soils of 30 virgin fields in six different areas of the Nebraska loess, made at the Minnesota Experiment Station, are reported.

It was found that "prairie loess soils in the surface foot show a steady decrease in phosphorus from the surface inch downward, independent of the

aridity of the climate in which they have formed. The concentration of phosphorus in the surface layers, while it may be attributed to the prairie vegetation, is not dependent upon a corresponding concentration of organic matter, the difference between the first and the twelfth inch being much the greater with the latter." The average phosphorus contents of the soils of the six areas were 0.141, 0.137, 0.147, 0.122, 0.132, 0.145, and 0.137 per cent.

In addition attention is drawn to the importance of considering the relative densities of soils when taking samples for comparisons of the phosphorus content of long cultivated soil with that of virgin prairie or prairie fields.

The mobilization of soil phosphoric acid under the influence of bacteria, IV, S. SEVERIN (S. A. SEVERIN) (*Věstník Bakt. Agron. Sta. V. K. Ferrein, No. 21 (1914), pp. 53-83*).—Continuing investigations previously reported (E. S. R., 31, p. 721), experiments with chernozem soil on the influence of the activity of certain soil micro-organisms on the solubility of phosphoric acid, carbon dioxide production, the quantitative variation of nitrate content, total nitrogen, and on bacterial numbers are reported.

In the first series three soil samples were used, one sterile, a second sterilized and inoculated with pure cultures of *Azotobacter*, and a third sterilized and inoculated with cultures of *Bacterium radicum* and *Azotobacter*. The phosphoric acid soluble in acetic acid increased in the inoculated soils from 8 to 14 per cent over that in the sterile soil.

In a second series one soil was sterilized, a second sterilized and inoculated with pure cultures of *B. fluorescens liquefaciens*, and a third sterilized and inoculated with pure cultures of *Bacillus mesentericus vulgatus*. The soluble phosphoric acid decreased about 5.8 per cent in the second soil and increased about 12.9 per cent in the third soil. Carbon dioxide production was about the same in both soils, but the numbers of *Bacterium fluorescens liquefaciens* far exceeded those of *Bacillus mesentericus vulgatus*. Both bacterial types were accompanied by a similar increase in soil nitrogen (about 20.6 mg. in 100 gm. of dry soil) and a slight decrease in nitrate content, the latter being more marked in the case of *Bacterium fluorescens liquefaciens*.

In the third series one soil was allowed to stand two months in its natural state, a second was sterilized, and a third was sterilized and inoculated with pure cultures of *Bacillus mycoides*. The bacterial numbers in the third soil differed but slightly from those in the first soil. Carbon dioxide production was four times as great in the first soil as in the third. *B. mycoides* showed no effect on the soil nitrate content or on the total nitrogen content, while both were decreased in the unsterilized soil. The soluble phosphoric acid decreased about 12.6 per cent in the unsterilized soil and increased about 4.2 per cent in the soil containing *B. mycoides*.

The influence of salts on the bacterial activities of the soil, J. E. GREAVES (*Soil Sci., 2 (1916), No. 5, pp. 443-480, figs. 4*).—Experiments conducted at the Utah Experiment Station on the influence of the chlorid, nitrate, sulphate, and carbonate of sodium, potassium, calcium, magnesium, manganese, and iron on ammonification in a productive sandy loam soil are reported.

It was found that the toxicity of the salts tested as determined by ammonification was controlled largely by the electro-negative ion. As a general rule, to which there were exceptions, the chlorids were the most toxic and nitrates, sulphates, and carbonates followed in the order of decreasing toxicity. The quantity of a salt which could be applied to a soil without decreasing the ammonia formed varied with the salt, and for the soil under investigation the order of decreasing toxicity of the salts was as follows: Calcium chlorid, calcium nitrate, sodium sulphate, potassium sulphate, magnesium nitrate, ferric

sulphate, potassium chlorid, magnesium chlorid, sodium chlorid, manganous chlorid, magnesium sulphate, manganous sulphate, potassium nitrate, ferric chlorid, manganous nitrate, sodium nitrate, magnesium carbonate, calcium sulphate, ferrous carbonate, ferric nitrate, potassium carbonate, sodium carbonate, manganous carbonate, and calcium carbonate. The last two were not toxic in any of the concentrations used. It was not necessarily those compounds which become toxic in the lowest concentrations which were most toxic in higher concentrations, as the toxicity of some salts increased more rapidly than the toxicity of others. It is considered evident that the increased osmotic pressure exerted by the salt added to the soil plays a great part in the retarding of the bacterial activity but that it is not the only factor.

"The common soil 'alkalis,' sodium chlorid, calcium chlorid, sodium sulphate—and the less common one—calcium nitrate, are very toxic to ammonifying organisms, and if present in soil to any great extent will greatly reduce the ammonia produced in such a soil.

"Calcium chlorid, calcium nitrate, potassium chlorid, potassium sulphate, magnesium nitrate, and sodium sulphate failed to increase the ammonia produced in a soil. All of the others, however, in some of the concentrations tested acted as stimulants. The extent of the stimulation and the quantity of salt necessary for maximum stimulation varied with the compound. In the order of increasing efficiency they are magnesium chlorid, manganous chlorid, potassium nitrate, ferric nitrate, magnesium carbonate, calcium sulphate, ferric sulphate, magnesium sulphate, sodium chlorid, sodium nitrate, ferrous carbonate, potassium carbonate, sodium carbonate, manganous carbonate, calcium carbonate, manganous nitrate, ferric chlorid, and manganous sulphate. Those compounds which are most active as stimulants to the higher plants are also most active in stimulating bacteria. . . .

"The quantity of sodium chlorid, calcium chlorid, potassium chlorid, and magnesium chlorid required to reduce the ammonifying powers of the soil to half normal is practically the same as the quantity necessary to reduce the growth of wheat to the same extent. The ammonifying organisms are apparently more resistant to the other compounds tested than are the higher plants."

Fifty-seven references to literature bearing on the subject are cited.

**A preliminary report on muck humus as a fertilizer and carrier of beneficial soil bacteria, T. F. MANNS and J. M. GOHEEN (*Dclaware Sta. Bul. 115 (1916), pp. 3-40, pls. 13*).**—It was found in the studies here reported that muck such as is found in the trucking districts of northern New Jersey, although normally low in beneficial soil bacteria (containing a limited number of clover nodule bacteria only), becomes a very favorable medium for the growth of such bacteria when properly balanced and reinforced, especially with basic substances. Forty different combinations or composts were tested in these studies. Among those giving the best results with nodule-forming bacteria were (1) muck 2,000 lbs., Thomas slag 15 to 50 lbs., carbohydrate 30 to 60 lbs., inoculating soil 25 lbs.; (2) muck 2,000 lbs., potassium carbonate 10 lbs., acid phosphate 50 lbs., calcium carbonate 100 lbs., carbohydrate 30 lbs., inoculating soil 25 lbs.; and (3) muck 2,000 lbs., ash 25 lbs., Thomas slag 25 lbs., calcium carbonate 100 lbs., carbohydrate 30 lbs., inoculating soil 25 lbs.

Satisfactory inoculation of the composts was secured with soil which had been found to give strong inoculation to each of the various groups of legumes. *Azotobacter chroococcum* was readily introduced by using soils from Colorado and North Dakota. The inoculated composts gave strong inoculation to the different groups of legumes when the latter were grown in sterilized sand cultures using the composts at the rate of 2 lbs. per acre of 2,000,000 lbs. Somewhat

stronger inoculation and growth were produced by using the compost at rates of 100 and 500 lbs. per acre. Crude carbohydrates and basic compounds such as ash and Thomas slag proved very efficient in developing nodule-forming as well as nitrogen-fixing and nitrifying organisms, ash being the most active mineral substance in this respect as indicated by crop response. Properly reinforced composts furnished all of the nitrogen required for the growth of rye and millet, being more effective in this respect than applications of cyanamid and guano.

The results reported show that the nodule-forming organisms of alfalfa, red clover, soy beans, and cowpeas may grow well in muck humus having a lime requirement of 5,000 lbs. per acre of 2,000,000 lbs.

Experiments on "humogen" (bacterized peat), J. A. VOELCKER (*Woburn Expt. Sta. Rpt. 1915, pp. 43-48, pl. 1; Jour. Roy. Agr. Soc. England, 76 (1915), pp. 357-362, pl. 1*).—Experiments with oats, peas, and mustard to determine the influence of bacterized peat when added in amounts of 1 part peat to 9 and 19 parts of soil are reported. Sodium nitrate in equivalent amounts with reference to nitrogen content was used for comparison. The following conclusions are drawn:

"Under conditions such as those obtaining in greenhouse cultivation, and where plants can be regularly watered and tended, a good preparation of 'humogen' may produce a very marked increase in the growth of the green parts of plants and in the growing of green crops, but it will show practically no benefit in the production of grain."

Contribution to the knowledge of the nodule bacteria (*Bacterium radicola*) in soils, P. KALANTAROV (P. B. KALANTAROW) (*Věstnik Bakt. Agron. Sta. V. K. Ferrein, No. 21 (1914), pp. 21-52*).—The work of others bearing on the subject is briefly reviewed and culture experiments with chernozem and productive loam soils are reported.

It was found that nodule bacteria require for their growth a minimum moisture content of about 30 per cent. The growth of *B. radicola* increased with greater moisture contents. In general a certain parallelism existed between moisture content of sterilized soil and the number of active nodule bacteria.

A study of the relation of other soil bacteria to *B. radicola* showed that *Bacillus mycoides* and *Bacterium fluorescens liquefaciens*, neither in soil nor culture media, exerted any appreciable influence on the growth of *Bacterium radicola*. On the other hand, *Bacillus mesentericus vulgatus* and *B. coli communis* showed a rather strong antagonism toward *Bacterium radicola*. The injurious influence of these organisms was weaker in soil. Inoculation of nodule bacteria into sterilized and unsterilized soils resulted in a slow, weak growth. A slight change in the physiological properties of the nodule bacteria isolated from the unsterilized soil was observed.

Studies of a number of bacteria isolated directly from soil led to the conclusion that only one of these could be placed with certainty in the *B. radicola* class.

The movement of nodule bacteria in sterilized soil was not very marked, averaging only about 0.52 cm. per day.

Are spore-forming bacteria of any significance in soil under normal conditions? H. J. CONN (*Jour. Bact., 1 (1916), No. 2, pp. 187-195*).—Experiments made at the New York State Experiment Station with three of the spore-forming bacteria always present in soil (*Bacillus mycoides*, *B. cereus*, and *B. megatherium*) are reported, which showed that "when soil infusion was heated before plating at a temperature (75-85° C.) high enough to kill the vegetative forms of bacteria, nearly, if not quite, as many colonies of these spore-forming

bacteria developed as when it was plated unheated. . . . This suggests that these bacteria occur in normal soil as spores rather than in a vegetative state. No increase in the total number of these organisms nor decrease in the number of their spores could be detected in a pot of soil to which fresh manure had been added.

"These results throw considerable doubt on the common assumption that these organisms are important ammonifiers in the soil. They raise the question as to what possible soil conditions favor their growth and multiplication."

**A possible function of Actinomycetes in soil, H. J. CONN** (*Jour. Bact.*, 1 (1916), No. 2, pp. 197-207).—Studies conducted at the New York State Experiment Station on the number and activities of Actinomycetes in fine sand, fine sandy loam, sandy loam, muck, stony loam, silty clay loam, loam, and gravelly loam soils are reported.

It was found that, in general, more colonies of Actinomycetes developed on plates made from sod soil than on those from cultivated soil. The average ratio between their numbers in neighboring sod and cultivated spots in the same soil type was slightly over 2:1. The maximum ratio was about 6:1. Actinomycetes averaged about 38 per cent of the total flora of sod soil, as determined by means of gelatin plates, but only about 20 per cent of the total flora of cultivated soil. In a study of three neighboring spots in a single soil type, it was found that with few exceptions Actinomycetes colonies not only appeared in greater numbers from sod than from cultivated soil, but also in greater numbers from old sod than from sod only two or three years old. "A probable explanation for this difference in numbers seems to be that Actinomycetes are active in the decomposition of grass roots."

**The relation of protozoa to certain groups of soil bacteria, T. L. HILLS** (*Jour. Bact.*, 1 (1916), No. 4, pp. 423-433).—Experiments conducted at the Wisconsin Experiment Station on the effect of protozoa on ammonification, nitrification, and nitrogen fixation in silt-loam soil are reported.

It was found that "in the soil cultures the presence of protozoa under the conditions of the experiments did not have any noticeable effect, detrimental or otherwise, on the processes of ammonification, nitrification, and free nitrogen fixation. In the case of the liquid cultures employed in the study of free nitrogen fixation the conditions were at an optimum for the development of the protozoa, and under these circumstances they limited bacterial activity as evidenced by the harmful effect on the fixation of free nitrogen. Undoubtedly under these conditions the protozoa were active in destroying the *Azotobacter* cells."

**Sterilization of the soil, R. S. CUNLIFFE** (*Estac. Expt. Agron. Cuba Bol.* 29 (1916), pp. 17, pls. 12).—This bulletin describes methods of soil sterilization used in Cuba and the results obtained.

The fire method is considered to be crude and uncertain. The use of anti-septics is expensive and is deemed inferior to the use of hot water and steam. The details of the method of steam sterilization practiced at the Cuba Experimental Station are presented, and it is concluded that this method has passed the experimental stage to an extent to make it of considerable practical value on plantations in Cuba, especially where the agriculture is intensive.

**Green manuring experiments, J. A. VOELCKER** (*Woburn Expt. Sta. Rpt.* 1915, pp. 15-17; *Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 329-331).—Green manuring experiments with corn on light soil are reported showing that the plowing in of leguminous crops, such as tares, did not give a return equal to that resulting from the plowing in of nonleguminous crops, such as rape or mustard. The soils receiving tares, however, contained more moisture, organic matter, and nitrogen than the nonleguminous soils.

**Availability of potash in certain orthoclase-bearing soils as affected by lime or gypsum**, L. J. BRIGGS and J. F. BREAZEALE (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 1, pp. 21-28).—Experiments are reported in which “samples of pegmatite and orthoclase were collected near Riverside, Cal., representing, respectively, types of the potash-bearing rock and mineral from which many of the citrus soils appear to be derived. These samples were finely ground and shaken for a number of days with aqueous solutions of calcium hydroxid and of calcium sulphate in graduated concentrations. The calcium-hydrate solutions did not modify the solubility of the potassium in either pegmatite or orthoclase. Gypsum solutions depressed the solubility of potassium in orthoclase, the quantity of potash in solution decreasing progressively as the concentration of the calcium sulphate increased.

“Similar tests were made upon a virgin soil of a granitic type from the experiment station near Riverside, Cal. The solubility of the potash was not measurably different in distilled water and in solutions of calcium hydrate or calcium sulphate.

“The addition of calcium sulphate to a citrus soil which had been under cultivation for some time and which was more granular and less weathered than the virgin soil decreased the solubility of the potash.

“The potassium content of wheat seedlings was practically the same when grown (1) in water containing finely ground orthoclase, and (2) in a saturated calcium-sulphate solution containing the same quantity of orthoclase. Similar experiments in which a citrus soil was used instead of orthoclase showed a decreased absorption of potassium by wheat seedlings in the presence of calcium sulphate.

“The experiments indicate that the availability to plants of the potash in soils derived from orthoclase-bearing rocks is not increased by the addition of lime or gypsum. In some instances a marked depression of the solubility of the potash in the presence of gypsum was observed.”

**Acidity of soils and lime requirements**, J. A. VOELCKER (*Woburn Expt. Sta. Rpt. 1915*, pp. 41-43; *Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 355-357).—The results obtained in these experiments are similar to those obtained in the 1914 experiments (*E. S. R.*, 35, p. 324).

**Chalking: A useful improvement for clays overlying the chalk**, E. J. RUSSELL (*Jour. Bd. Agr. [London]*, 23 (1916), No. 7, pp. 625-632, pl. 1, fig. 1).—This is a brief account of the method and cost of obtaining and using chalk on stony clay soils in the English counties surrounding the city of London, together with a brief review of results showing the effect of chalk on different crops.

**The relation of lime to magnesia in soils**, J. A. VOELCKER (*Woburn Expt. Sta. Rpt. 1915*, pp. 37-41, pls. 2; *Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 351-355, pls. 2).—Experiments on the effect on wheat of adding caustic lime and calcium carbonate to soils containing an excess of magnesia and of adding caustic magnesia and magnesium carbonate to soils containing an excess of lime are reported.

In the first case the conclusion was reached that “lime may be added in considerable excess of the magnesia present provided it be put on in the form of carbonate of lime and not as caustic lime.” In the second case the results were not conclusive.

**Influence of magnesia on wheat**, J. A. VOELCKER (*Woburn Expt. Sta. Rpt. 1915*, pp. 17-20; *Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 331-334).—Experiments with wheat on two 1/20-acre plats of soil containing 0.46 per cent of calcium oxid and 0.28 per cent of magnesium oxid, to which ground magnesia was added at the rate of 4 tons per acre, showed that the wheat on

the magnesia plat was darker in color, stronger, and better tillered out than on the untreated plat. The total yield was also greater on the magnesia plat. On plats of previous experiments, it was found that the wheat crop showed after three years a slight advantage from the application of magnesia.

**The influence of strontium salts on wheat, J. A. VOELCKER** (*Woburn Expt. Sta. Rpt. 1915, pp. 30-37, pls. 2; Jour. Roy Agr. Soc. England, 76 (1915), pp. 344-351, pls. 2*).—Experiments on the influence of the sulphate, nitrate, hydrate, chlorid, and carbonate of strontium on wheat in light unproductive soil when added in amounts equivalent to 0.05 and 0.1 per cent of strontium are reported.

It is concluded that "strontium in the form of the sulphate, the hydrate, and the carbonate, is, when given up to 0.1 per cent, practically without effect either on the germination of the seed or the increase of the crop. Strontium used in the form of nitrate produces an increase of crop, but this can not be attributed to the presence of strontium. Strontium applied as chlorid has a retarding effect on germination and, when used in quantity approaching 0.1 per cent of strontium, has a distinctly toxic effect."

Experiments on the influence of boric acid and borax on wheat when added in amounts equivalent to 0.1, 0.05, 0.02, 0.01, 0.005, 0.001, 0.0005, 0.00025, and 0.0001 per cent of boron and on barley when added in amounts equivalent to from 0.001 to 0.0001 per cent boron are also reported. It is concluded that "germination is retarded when over 0.003 per cent of boron is used, and even 0.001 per cent, more especially with borax, seems to delay germination. Over 0.001 per cent of boron, either as boric acid or borax will prevent plants from developing and forming grain. A toxic influence is shown with 0.0005 per cent of boron, but with quantities not exceeding 0.00025 per cent there is a slightly stimulating effect. The effects generally are more marked with borax than with boric acid."

**Action of manganese, iron, and copper on the growth of plants, H. VAGELER** (*Landw. Vers. Stat., 88 (1916), pp. 159-242; abs. in Jour. Chem. Soc. [London], 110 (1916), No. 644, I, p. 457; Chem. Abs., 10 (1916), No. 20, p. 2609*).—Water culture experiments with oats, lupines, and beans, pot experiments with oats and lupines, and field experiments with oats are reported.

"In the water cultures the amounts of manganese sulphate, iron sulphate, and copper sulphate employed were, respectively, 0.482, 0.556, and 0.042 gm. per liter. No stimulating effects were observed in the water-culture experiments, and addition of calcium and sodium chlorids failed to diminish the poisonous effects, which were much the greatest in the case of copper sulphate. Beans were much less sensitive to copper than oats. In the pot experiments iron and copper slightly reduced the yield of oats, especially in sand, while manganese had no effect either in sand or in loam. Lupines were benefited both by iron and copper but not by manganese. In the field experiments the three metals had practically no effect."

**Concerning the use of commercial fertilizers in 1916** (*Vermont Sta. Circ. 10 (1915), pp. 16*).—This is a summary of the opinions expressed at a meeting of the directors of the experiment stations of the North Atlantic States as to the best procedure in maintaining soil fertility in those States in view of the present abnormal fertilizer situation.

**Analyses of commercial fertilizers** (*New York State Sta. Bul. 425 (1916), pp. 413-471*).—This bulletin gives the results of analyses by the station of samples of fertilizers collected by the commissioner of agriculture of New York during 1916. Attention is called to the fact that because of the abnormal trade conditions no attempt is made to give approximate commercial valuations of the fertilizers.

Official report on commercial fertilizers licensed, inspected, and analyzed during the year 1914 (*Agr. Com. Ohio, Off. Rpt. Com. Fcrt., 1914, pp. 273*).—In addition to a large amount of general information regarding the selection, purchase, and use of commercial fertilizers in Ohio, this report contains the results of actual and guaranteed analyses of 726 samples of fertilizers and fertilizing materials offered for sale in Ohio during 1914.

Commercial fertilizers, W. B. CADY (*Porto Rico Bd. Agr. Expt. Sta. Bul. 16 (1916), pp. 12*).—This bulletin gives a brief general discussion of fertilizers in relation to crop production, and reports the results of actual and guaranteed analyses and valuations of 106 samples of fertilizers and fertilizing materials offered for sale in Porto Rico.

Commercial fertilizers, J. L. HILLS, C. H. JONES, and G. F. ANDERSON (*Vermont Sta. Bul. 198 (1916), pp. 5-49*).—This bulletin reports the results of actual and guaranteed analyses of 168 samples of fertilizers and fertilizing materials, representing licensed brands collected for inspection in Vermont during 1916, together with a discussion of results and other data. It was found that 82 per cent of the brands analyzed met their guarantees. Owing to abnormalities in the trade in crude chemicals no valuations are given.

### AGRICULTURAL BOTANY.

Hereditary reaction system relations—an extension of Mendelian concepts, R. E. CLAUSEN and T. H. GOODSPEED (*Proc. Nat. Acad. Sci., 2 (1916), No. 4, pp. 240-244*).—As preliminary to a more detailed statement to appear later, the authors report briefly some results of observation and experimentation carried on for about ten years at the university of California on the monotypic species *Nicotiana sylvestris* and a number of the varieties of *N. tabacum*.

When any one of these varieties is crossed with *N. sylvestris*, the  $F_1$  hybrid nearly, or completely, reproduces on a larger scale the characters of the Tabacum variety used in the cross, somatogenesis in these cases appearing to be dominated by the Tabacum system as a unit. It is thought that if these  $F_1$  hybrids be considered to represent the reaction end-product of two fundamentally dissimilar reaction systems, the relations of the two systems, as here manifested, indicate a rather extensive mutual incompatibility of the elements of the two systems.

This deduction is supported by the fact that these hybrids produce only a few functional ovules, the number being apparently constant within rather narrow limits. These functional ovules are considered to represent the *N. tabacum* and *sylvestris* extremes of a recombination series, the vast majority of the members of which fail to function on account of being built up of incompatible elements from the two systems.

The deduction is made that the type of behavior displayed by species hybrids may be considered as dependent upon the degree of incompatibility of the reaction systems involved, sterility in such cases being merely a logical consequence of such incompatibility and an expression of its extent. The implications of the conceptions of such a reaction system are discussed.

On the composition of a factorial formula for zygotes in the study of inheritance of seed characters of *Zea mays* with notes on seed pigments, K. FUJII and Y. KUWADA (*Bot. Mag. [Tokyo], 30 (1916), No. 351, pp. 83-88*).—The authors report studies on two conditions which, it is thought, may account for disagreements between theoretical expectations and experimental results met with by various investigators in studying inheritance of seed characters in maize.

In connection with a discussion of the triploid nature of the endosperm in maize, a new formula is proposed for the  $F_1$  zygote,  $AAa$  being the zygotic formula supposed to apply when the plant with the gametic formula  $A$  has been taken as the maternal plant, and  $aaA$  when the plant with the gametic formula  $a$  has been taken as the maternal plant. The dominant factor  $A$  being duplicated in the first of these cases, seeds of the darker blue or black color are produced, while that factor is single in the second case, giving light blue.

The difficulties of interpretation of zygotic distribution concerning colors on an ear of dihybrid and polyhybrid maize plants are supposedly due to several conditions, one of which is noted above. Another is believed to be the occurrence of two kinds of similar pigments, which were detected by microchemical and macrochemical tests briefly described. These may occur in the same seeds and may impair the reliability of genetic studies in such cases.

Observations on inheritance of sex-ratios in *Mercurialis annua*, C. YAMPOLSKY (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 69-74).—Observations extending to the  $F_2$  generation of *M. annua*, and still in progress, appear to negative the assumption that either one or the other of the sexes has two kinds of gametes.

Inheritable variations in the yellow daisy (*Rudbeckia hirta*), A. F. BLAKESLEE (*Mem. N. Y. Bot. Gard.*, 6 (1916), p. 89).—Among the variations noted, most of which appear to be inheritable in the wild yellow daisy, are such as relate to the absence or presence, somewhat definite numbers, position, width, shape, and coloration of rays; to the shape, size, and color of the disk; and to such vegetative characters as height, branchings, fasciations, and leaf size and shape. Other characters are being investigated.

A tetracotyledonous race of *Phaseolus vulgaris*, J. A. HARRIS (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 229-244, figs. 3; *Proc. Nat. Acad. Sci.* 2 (1916), No. 6, pp. 317, 318).—An account is given of the study of a teratological race of *P. vulgaris* which originated in the progeny of a plant grown in 1907, all the characteristics of its origin being characteristic of de Vriesian mutation.

The race has proved to be practically constant for the four generations during which the offspring have been studied. While it is designated as tetracotyledonous for lack of a better descriptive term, the cotyledons (most frequently four in number) are highly variable, the primordial leaves being still more so. A low degree of correlation has been noted between cotyledon number and leaf number.

Self, close, and cross fertilization of beets, H. B. SHAW (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 149-152, pl. 1, fig. 1).—Having found that under isolation tents of material having meshes as fine as the finest used by European writers fertilization occurred to the amount of about 23 per cent in case of seed beets, and having concluded that cross-fertilization is usually possible owing to the coarseness of the meshes in the cloth available for this purpose, the author separated his growing seed beets by intervals of at least two miles. The highest resulting percentage of seed in no case rose above 2.29 per cent. Several plants which remained sterile showed a development otherwise normal.

Experiments carried out are thought to show that in cross-pollination between two different plants of the same progeny the percentage of potential fertilization appears to be 100 per cent, being limited in practice only by the technique. Close pollination between flowers of different stems of the same plant resulted in fertilization in 8.54 per cent of the cases and in carpel stimulation (to growth) in 3.47 per cent. Close pollination between flowers of different spikes resulted in fertilization in 5.23 per cent of the cases and in carpel stimulation in 5.8 per cent. Close pollination between different flowers of the same spike resulted, according to technique, in pollination in from 2.7 to 2.63 per cent and in stimulation in 1.43 to 5.26 per cent of the cases. Self-pollination resulted in neither fertilization nor carpel stimulation in any case.

It is thought probable that minute biochemical differences exist which increase in magnitude as the physical intimacy or relationship decreases.

Self-pollinations and cross-pollinations in *Cichorium intybus* with reference to sterility, A. B. STOUT (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 333-454, pl. 1).—The author, concluding an extensive report and discussion of pollination studies dealing more particularly with *C. intybus*, states that a marked degree of similarity in constitution between male and female gametes is the most fundamental necessity to sexual fertility. Obvious anatomical differences are deemed to a large degree superficial and unessential.

The presence of both self-fertility and cross-fertility within a nondimorphic species or strain, as in *C. intybus*, is considered to show that incompatibility is fundamentally independent of visible differentiation. The evidence on the whole favors the view that for successful fertilization the element of similarity in cell organization and in the physical, chemical, idioplasmic, and structural properties of all the cells and tissues involved is more important than any dissimilarity that can be associated with sex differentiation.

The results in chicory also show that the development of self-incompatibility is not closely correlated with conditions in the immediate parentage. In physiological incompatibilities that appear in the selfing and crossing in such nondimorphic species as *C. intybus* and *Cardamine pratensis*, also in such dimorphic species as *Primula sinensis*, it appears that the grade of sex differentiation within the individual may involve sufficient relative dissimilarity to limit or prevent pollination.

Studies on the blooming of hemp, G. HAVAS (*Kísérlet. Közlem.*, 18 (1915), No. 5-6, pp. 908-919, pls. 2, figs. 5).—The modes of succession in the appearance of blooms at different levels of both male and female plants of *Cannabis sativa* are described. It is stated that blooming and pollen dispersal by the male flowers (the period between which occupies about seven hours) occur mainly during the night and morning, a minimum rate prevailing in the latter part of the night and the forenoon.

The persistence of the style on fruits, C. CAMPBELL (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 3, pp. 178-183, figs. 2).—Cases are described, chiefly in lemons, in which the persistence and development of the style after fertilization resulted in a deformed fruit. It is thought that in case of relatively rapid development just after pollination the formation of a fission layer proceeds normally, while in case of slower development this does not occur and the persistent style develops as part of the fruit.

The determinative action of environic factors upon *Neobeckia aquatica*, D. T. MACDOUGAL (*Flora [Jena]*, n. ser., 6 (1914), No. 3, pp. 264-280, figs. 14).—Experimentation through which *N. aquatica* has been carried, including the keeping of cultures as terrestrials or aquatics in environments and under conditions differing very widely, has shown that this plant, which endures an extremely wide range of conditions, is capable of considerable modifications in several directions by alternations of environment. The changes appear not to be adaptive in many cases, though determined by environment to a much greater degree than in case of *Proserpinaca*, *Sium*, or probably any other so-called polymorphic species, yet the reaction to such external agencies is not considered to be a direct or physical adjustment.

Plant ecology and the new soil fertility, C. B. LIPMAN (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 319-321).—This is a brief discussion of the benefit considered to be derivable from closer cooperation between plant ecologists and soil scientists regarding such factors as the composition and concentration of

the soil solution, balance between the soil solution components, forms of nitrogen suitable for plants, the influence of quantity and quality of organic matter, the proper basicity or acidity for a given plant, and the mutual influence of plants growing together.

Growing plants in large containers under control conditions, R. C. WRIGHT (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 2, pp. 113-116, pl. 1, figs. 2).—A description is given of an arrangement adapted to the growing of plants under controlled and yet nearly natural conditions. It comprises a soil container in bucket form, of heavy corrugated iron, 15 in. in diameter by 13 in. deep, provided with drainage holes in the bottom and placed in a well made by sinking terra cotta sewer tiles to within 2 in. of the surface of the ground. The cans are handled and weighed by means of a block and tackle and a movable derrick. The data obtained are presented and discussed. The temperature conditions in the cans are said to be kept fairly uniform and to be practically those of natural soil.

An apparatus for aerating culture solutions, P. WEATHERWAX (*Proc. Ind. Acad. Sci.*, 1914, pp. 157-160, fig. 1).—It is stated that the requirements incident to experiments on various phases of plant physiology have led to the development of an apparatus for the maintenance of a constant stream of air for several days. This has proved to be very efficient for that purpose and is now being used very successfully in the aeration of culture solutions. The principle is that of the Sprengel mercury pump, the adaptations of which are described. It is claimed that the economy and the wide range of adjustment in this instrument are such as to allow its use for many other purposes.

Preliminary report on synthetic media, C. J. T. DORYLAND (*Jour. Bact.*, 1 (1916), No. 2, pp. 135-152).—The term synthetic media is here used to mean one containing only compounds of known composition and structure, including both nutrient solutions and solid (synthetic) media formed by the precipitation of an agglutinant from compounds of known composition and structure. The author reports on an attempt, by the use of definite sources of energy and nitrogen, to exclude all species but those which can use the particular source employed in each case, thus limiting greatly the number of groups, also that of individuals, present in any case. The schematic arrangement presented is tentative and is limited to water-soluble compounds. Sixteen media have been tested up to the present time, promising results having been obtained.

The mechanism and conditions of growth, D. T. MACDOUGAL (*Mém. N. Y. Bot. Gard.*, 6 (1916), pp. 5-26, pl. 1, figs. 4).—The author presents results of experimentation with the platyopuntias, thought to have an important bearing on the main problems of growth, which requires building material of a highly specific character, as exemplified in the author's results from studies with the polymorphous plant *Neobeckia* (see p. 523).

He states that joints or segments of the platyopuntias accomplish nearly all of their total enlargement during 60 to 100 days of the initial season in the Tucson climate. Enlargement and secondary growth may take place as determined by branching and environic factors in the succeeding seasons, the changes in volume of joints, including daily reversible alterations which are described, amounting to 1/250 of the total length. The general features of the daily growth record suggest that enlargement takes place after the smothering or clogging acids have been broken down, and that it ceases when the supply of building material is greatly reduced.

The direct action of light on protoplasts and on body temperatures is to be described in a later paper.

**The nature of mechanical stimulation**, W. J. V. OSTERHOUT (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 4, pp. 237-239, fig. 1).—The author observed that when a cell of the marine alga *Griffithsia bornetiana* was touched near one end, the surfaces of the chromatophores in this region became permeable to their red pigment. This soon began to diffuse out into the surrounding protoplasm, rendering the other chromatophores, as successively reached, permeable in like manner, a wave of stimulation thus progressing until the other end of the cell is reached by the wavelike changes. It is thought that the alterations set up in the successive cells, resulting in diffusion of red pigment (and probably other substances), are chemical in their nature.

The disturbance is thought to originate as a mechanical rupture of the surface layer of the chromatophore, as a number of cellular structures are known to possess surface layers of great delicacy. Reactions are supposed to occur between the diffused contents and other substances as encountered. Physical alterations in the protoplasm may thus give rise to chemical changes, and responses to contact and mechanical or gravitational deforming stimuli may thus be explained. In this conception of mechanical stimulation the essentials are substances separated by semipermeable membranes, production of a rupture in these which is not at once repaired, and a resulting reaction which produces the characteristic visible response to the stimulus.

**Energy transformations during the germination of wheat grains**, LUCIE C. DOYER (*Rec. Trav. Bot. Néerland.*, 12 (1915), No. 4, pp. 369-423, pls. 2).—Giving a bibliography and more extensive data than in a previous report (*E. S. R.*, 35, p. 632), the author states that in the germination of wheat grains the loss of energy increased for seven days, particularly on the third day. The loss during the first two days, when imbibition was relatively important, was comparatively small.

Heat evolution also increased with the progress of germination, the increase being most marked on the third and the fourth day, and the rate being increased with a rise of temperature up to 35° C. (95° F.), the heat development more than doubling with a rise of 10°. At 40° heat development began to diminish. Respiration was increased during germination at a temperature of 25°, the increase being greater in the early period of germination. During the first six days of germination at 25° the amount of heat given up was less than the loss of energy set free by respiration. Heat development had its optimum at 35°, which is higher than the optimum for respiration. There appears, therefore, to be no constant relation between heat development and respiration.

**A study of the relation of soil moisture to transpiration and photosynthesis in the corn plant**, T. G. YUNCKER (*Plant World*, 20 (1916), No. 6, pp. 151-161, figs. 4).—Experiments to determine the relation between the amount of transpiration and photosynthesis in corn plants and the degree of soil moisture in which they were grown are described.

The author reports, in regard to three tests made, that the plants in soil watered to 25 per cent of saturation weighed the most per unit of leaf area, those in that at 65 per cent the least, while those at 45 per cent showed an intermediate increase of weight and inferentially of photosynthetic activity. The water requirement was less for plants in the drier than for those in the wetter cultures. Transpiration rates showed the same relation to moisture content as did the water requirement. It thus appears that the amount of organic matter formed is not proportional to transpiration.

**On the relation between the rate of root growth and oxygen**, W. A. CANNON (*Abs. in Science*, n. ser., 44 (1916), No. 1143, p. 761).—A series of experiments is reported in which the roots of *Prosopis vultina* and *Opuntia versi-*

color were exposed to atmospheres of pure carbon dioxid and of atmospheric air so diluted with carbon dioxid that the mixture contained from 5 to 25 per cent of oxygen.

The roots of the species were found to maintain a feeble growth rate in an atmosphere containing as little as 5 per cent of oxygen, but growth stopped in both species in pure carbon dioxid. Recovery from the asphyxiation occurred sooner in *Prosopis* than in *Opuntia* and in both sooner at high than at low soil temperatures. The results are believed to indicate that the response of the roots of *Opuntia* to a diminished oxygen supply, such as occurs with increasing depth below the surface of the ground, is a contributory factor in bringing about the superficial placing of roots.

The embryo sac and pollen grain as colloidal systems, F. E. LLOYD (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 561-563).—The author reports very briefly on certain observations made on the behavior of protoplasm, which is recognized as a hydrophile emulsion colloid, showing alterations corresponding to changes in water content and space relations of the dispersoids and the disperse medium. He admits that it is not possible at the present stage of knowledge to discount the views of Borowikow (E. S. R., 33, p. 28) that the agents concerned in swelling are also concerned with growth, since we do not yet know how swelling, shrinking, and coagulating reagents affect the relation of change of hydration to the capacity of protoplasm to secrete and to hold water within the vacuoles, the solutions, suspensions, etc., of which are unknown but complex as regards composition and behavior.

Contents of amylase in ripening seeds of horse beans, A. BLAGOVIĚSHCHENSKĪĪ (BLAGOVESCHTCHENSKI) (*Zuhr. Russ. Fiz. Khim. Obshch., Chast Khim.*, 47 (1915), No. 6, pp. 1529-1532; *abs. in Jour. Chem. Soc. [London]*, 110 (1916), No. 639, 1, p. 109).—It was found that in seeds of *Vicia faba minor* the amount of amylase present corresponded approximately to the rate of starch accumulation. This is considered as evidence of the synthesizing action of amylase in the ripening seeds, the lack of complete parallelism being attributed to the loss of some of the starch from the assimilatory organs.

Present status of the problem of the effect of radium rays on plant life, C. S. GAGER (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 153-160).—The evidence is here briefly reviewed, as obtained by various investigators including the author, since the publication of his previous summation of the known related facts (E. S. R., 20, p. 1124). It is considered to justify the broad inference that although radio-activity may act as a stimulation to plant growth, our present knowledge regarding the cause and the effects of that agent warrants little, if any, hope of its profitable utilization in practical agriculture.

The influence of ultraviolet rays on phosphorescent bacteria, F. C. GERRETSEN (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1915), No. 17-23, pp. 660, 661).—Reporting the results of some preliminary experiments, the author states that *Photobacterium phosphorescens* exhibited luminosity and the function proper to catalase for several hours after being killed by means of ultraviolet rays.

The influence of inorganic salts on the development of Actinomycetes, III, F. MÜNTER (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1916), No. 24-25, pp. 673-695, figs. 9).—Continuing previous work (E. S. R., 31, p. 324), the addition of 5 per cent of potassium chlorid, sodium chlorid, potassium nitrate, and sodium nitrate to nutritive media was found to increase growth markedly, but decreased spore formation in Actinomycetes. The addition of 10 per cent arrested development in nearly all cases. The corresponding salts of magnesium hindered growth, and magnesium carbonate arrested it completely. Spore formation was increased by small but decreased by larger additions of the chlorids, nitrates, and carbonates of calcium, barium, and strontium, the carbonates,

however, appearing relatively indifferent. Silver and copper were very unfavorable to growth, mercury less injurious, and lead and iron salts the least hurtful to vegetative growth. Low concentrations of the nutritive components hastened spore formation.

**Note on the nitrogen nutrition of mold fungi,** W. BRENNER (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1915), No. 9-13, pp. 304, 305).—Besides a few corrections and comments on statements made in the previous article (E. S. R., 32, p. 327), a few additions, of contributions not later than 1913, are made to the bibliography previously given.

**Variations in nodule formation,** L. T. LEONARD (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 2, pp. 116-118).—In view of the observed differences in the degree of inoculation exhibited by legume varieties, and even by individual plants, exposed to the nodule-forming organism, the author tested 19 varieties of soy beans with cultures taken from one of them. He obtained nodules in case of each variety, only one requiring a third inoculation.

**The present state of our knowledge of the physiological significance of the mycorrhizæ of trees,** D. L. PETH (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 9 pp. 1138-1151).—The author concludes a review of the studies and views of various authors regarding the real nature of the relations between the roots of trees and the mycorrhizæ found in connection therewith by stating that the results of 30 years of scientific research, at least so far as arborescent plants are concerned, have not led to either confirmation or rejection of the theory of mutuality.

## FIELD CROPS.

**The use of checks and repeated plantings in varietal tests,** F. J. PRITCHARD (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 2, pp. 65-81, figs. 3).—This article is a discussion of the methods used in field-variety tests. The experiments were conducted with sugar beets in an attempt to determine three things: (1) The optimum frequency of checks; (2) whether the best frequency of checks is efficient enough for satisfactory comparisons; and (3) the measure of the comparative effect of repeated plantings upon the experimental error. The results are discussed in detail, and the general conclusions drawn are as follows:

(1) The practice of dispensing with check rows and using the mean of all progeny rows as a standard of comparison appears to be less efficient than the employment of frequent checks; (2) check rows 32 in. from the progeny row varied less than those 64, 96, 128, and 160 in. distant; when the probable error was duly taken into account the last four distances appeared to be good checks; (3) the use of alternate rows as checks did not offset the variability in yield due to irregularities of the soil; and (4) the experimental error was reduced about 50 per cent by means of 10 replications and alternate check rows.

**The mode of pollination in some farm crops,** M. N. POPE (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 4, pp. 209-227).—This article is a review of the literature, corn, wheat, oats, barley, rice, rye, and flax being discussed specifically. A bibliography of the literature cited is included.

**The identification of grasses by their vegetative characters,** L. CARBIER (*U. S. Dept. Agr. Bul.* 461 (1917), pp. 30, figs. 60).—Following the work of other investigators the author presents a plan of classification to identify grass seedlings based somewhat on that of Percival (E. S. R., 12, p. 719), but including a larger number of grasses. The botanical characteristics of grasses before the blooming stage are described and the use of the key discussed.

The small grains have been placed in a separate group in order to emphasize the differences that occur among themselves. The grasses studied are all common to the eastern United States, the distinctively western species being excluded.

In addition to the analytical key, detailed descriptions of 48 seedling grasses and 8 small grain seedlings are given and illustrated.

**Dry farming in Utah**, F. S. HARRIS and A. D. ELLISON (*Utah Sta. Circ. 21* (1916), pp. 3-35, figs. 15).—This circular is a general discussion of dry farming in Utah, with recommendations regarding the selection and management of land for dry-farming purposes. Dry-farm crops for Utah are listed as follows: Wheat, rye, oats, barley, emmer, potatoes, corn, peas, beans, alfalfa, the sorghums, and certain miscellaneous crops, as the grasses, clovers, flax, etc. Other points discussed are seed selection, cultural methods, cropping systems, storage of water in the soil, irrigation as a supplement to dry farming, and dry-farm equipment. A general summary of the discussion is as follows: (1) Dry farms should not be located in regions having less than 12 in. of rainfall a year; (2) the soil should be uniform and deep and should support a good natural growth, preferably of sagebrush; (3) new land should be plowed a year before planting a dry-farm crop and fallowed each alternate year; (4) deep plowing and thorough tillage during the following year are necessary to conserve moisture; and (5) irrigation is often a valuable supplement to dry farming.

**A twenty-year comparison of different rotations of corn, potatoes, rye, and grass**, B. L. HARTWELL, S. C. DAMON, ET AL. (*Rhode Island Sta. Bul. 167* (1916), pp. 38).—This reports the results of investigations with different crop rotations, and fertilizer studies in connection with them, which were begun in 1893. Previous reports have appeared, giving the methods of planting, care, fertilizer formulas, and details regarding each rotation (E. S. R., 7, p. 396; 12, p. 1030; 13, p. 34; 15, p. 144; 16, p. 150; and 21, p. 730).

The rotations were as follows: Three-year—potatoes, rye and rowen, and grass; 4-year—potatoes, rye and rowen, grass, and corn; 5-year—potatoes, rye and rowen, grass, grass, and corn; 5-year—potatoes, rye, grass, grass, and corn; and 6-year—potatoes, rye and rowen, grass, grass, grass, and corn. In the early spring 3 lbs. of alsike and 4.5 lbs. of red clover per acre were sown on all plats except those of the second 5-year rotation.

The cultural methods practiced toward the end of the 20-year period are discussed for each crop, and the fertilizer treatments for the various crops for the entire period are given in tabular form. The yield of each crop for each year of the experiment is also tabulated and the averages for each rotation briefly discussed.

The average yields per acre for all crops at the time of harvesting were 207 bu. of potatoes over 2 oz.; 17 bu. of rye, 1.57 tons of straw and 0.66 ton rowen; 3.16 tons first-year hay and rowen; 3.08 tons second-year hay; and 58 bu. hard corn. The highest yield of marketable potatoes, 223 bu., was secured from the 6-year rotation, the 5-year rotation without legumes being second with 216 bu. The highest yield of rye grain, 19 bu., and straw, 1.7 tons, was secured from the 3-year rotation. The highest hay yields were secured from the 6-year rotation regardless of the number of years removed from seeding. The highest yields of corn, 63 and 61 bu., were secured from the 4 and 6 year rotations, respectively.

The comparative effect of manure and chemical fertilizers on yields is discussed, and the conclusion drawn that there was no decided difference in the corn yields when 4 cords of stable manure or chemical fertilizers, furnishing 30 lbs. of nitrogen, 80 lbs. of phosphoric acid, and 60 lbs. of potash, were used.

The data also failed to show that there was any positive difference in the yield of the potatoes following the corn.

For the purpose of comparing the rotations the crops were given arbitrary values as they were harvested and, after deducting charges for production and fertilizers, the resulting net return used as a basis for comparison. The 6-year rotation returned the highest average annual net profit of \$16.45, with the 3-year rotation second and giving a net return of \$14.26. The lowest return was secured from the 5-year rotation without legumes and amounted to \$11.66.

Nitrogen determinations were made on the surface soil from each plat in the rotations in 1912. All the plats of the 6-year rotation were noticeably high in nitrogen, but further observations are deemed necessary before drawing definite conclusions. The average nitrogen content for all rotations was 0.2342 per cent.

[**Field crops**] *Off. Bul. Wyo. Bd. Farm Comrs., 1914, pp. 32-65, 78-82, 90-108, figs. 15*).—Notes are given on the cultivation and agricultural value under dry-farm conditions of wheat, oats, barley, emmer, rye, flax, alfalfa, peas, sweet clover, corn, sweet sorghum, Sudan grass, brome grass, millet, potatoes, rape, sand vetch, and beans. Practically all these crops have proved valuable for this section with the exception of winter oats, winter barley, and emmer. Rate and date of seeding tests and variety tests are in progress with most of the above-named crops.

The winter wheat varieties recommended at the present time are Turkey, Kharkov, and Crimean, and for spring wheat varieties the durum wheats and Spring Ghirka. The preferred rate and date of seeding spring wheat are from 2 to 4 pk. between April 15 and May 1. Kherson and Sixty-Day are deemed the best oat varieties, and should be sown at the rate of about 1 bu. per acre about April 15. Spring barley sown at about April 15 at 1 bu. per acre gave the best results, and Ouchac and Hannchen were the most satisfactory varieties. Flax should be sown at the rate of 20 lbs. per acre about June 1. The Kursk millets are deemed best for seed and forage production. The highest yielding potato varieties were Irish Cobbler, Blue Victor, and Early Ohio. The corn variety tests have not proved very satisfactory owing to the difficulty of securing maturity.

**Field experiments, 1915** (*Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 2, pp. 237-290*).—The results of field experiments for 1915 are reported and discussed with barley, meadow hay, potatoes, mangles, oats, turnips, and wheat. All the crop experiments except those with barley included tests on peat soil, with special reference to the fertilizer requirements of the various crops. Several experiments with liquid manure are also reported.

**Catch crops** (*Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1915), No. 1, pp. 120-127*).—A list of forage plants available for autumn catch crops is given.

**Forage plants** (*Bol. Min. Agr., Indus. e Com. [Brazil], 4 (1915), No. 3, pp. 68-72*).—This article contains a brief discussion of the cultural habits and forage value of several plants native to Brazil.

**The history of Kentucky blue grass and white clover in the United States**, L. CARRIER and KATHABINE S. BORT (*Jour. Amer. Soc. Agron., 8 (1916), No. 4, pp. 256-266*).—This article reviews references to the natural vegetation of America in an effort to trace the origin of Kentucky blue grass (*Poa pratensis*) and white clover (*Trifolium repens*). The evidence seems to indicate that these two plants were introduced into the United States.

**Corn improvement in the Philippines**, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.], 8 (1915), No. 3, pp. 216-225, pls. 3*).—This paper discusses the development of the corn crop in the Philippines, with special reference to the

improvement of native flint varieties. A detailed report is given of ear-to-row experiments. Considerable work has been done in developing strains by means of self-pollination, employing the method of Collins and Kempton, previously described (E. S. R., 26, p. 535).

Sea Island cotton, W. A. ORTON (*U. S. Dept. Agr., Farmers' Bul. 787 (1916), pp. 40, figs. 13*).—A revision of Farmers' Bulletin 302 (E. S. R., 19, p. 332).

West Indian Cotton Conference, 1916 (*West Indian Bul., 15 (1915), No. 4, pp. 235-329, pl. 1, figs. 2*).—A report of this conference is given.

Flax seed for 1916 sowing (*Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 2, pp. 312-315*).—Owing to a scarcity of seed a number of importations of flax have been made from the United States, Canada, Russia, France, Holland, Argentina, Japan, Siberia, and Yorkshire and the results of the tests reported. The imported varieties recommended for use were from Holland, Russia, Yorkshire, Canada, and France.

Concerning the oat crop, J. L. HILLS (*Vermont Sta. Bul. 197 (1916), pp. 46-72*).—This article is a compilation of general information relating to the production of oats as a Vermont roughage.

Observations on some degenerate strains of potatoes, F. C. STEWART (*New York State Sta. Bul. 422 (1916), pp. 319-357, pls. 12*).—A number of potato plants from seed grown at Honeoye Falls, N. Y., by the U. S. Department of Agriculture, showed signs of abnormality early in the summer, the trouble being diagnosed as curly dwarf. This bulletin deals with the behavior of those plants and their progeny in 1915, together with some observations on other degenerate strains of potatoes. The object of the study was to add to the knowledge of the forms of degeneration known as leaf roll, curly dwarf, mosaic, and spindling sprout and their relation to the selection of seed potatoes. The bulk of the observations were made on Green Mountain, Jr., with additional notes on the following varieties: State of Maine, Carman No. 2, Long Island Wonder, Knoxal, Rural New Yorker No. 2, Late Victor, Ionia, Pride of Vermont, Green Mountain, and an unknown variety. Careful notes were made of the parent stock and great care exercised in regard to the performance of the progeny.

The striking feature of the observations was the frequency with which the progeny of plants with apparently normal foliage and high yield suddenly degenerate into worthless dwarfs affected with various forms of degeneration. The conclusion is reached that these degenerations (leaf roll, curly dwarf, and mosaic) are closely related disorders, due to the same general, undetermined cause, all transmitted through the seed tubers, the progeny of affected plants almost always becoming affected. Spindling sprout is not correlated with leaf roll, mosaic, or curly dwarf, and its heredity is still undetermined. Evidence is lacking to show that any one of the four forms of degeneration named is communicable from one plant to another except through the seed tubers. They were not due to parasitic organisms nor to unfavorable soil or weather conditions of the current season.

Plants from different tubers of the same plant were found generally similar, and plants from different eyes of the same tuber usually resembled each other closely, although exceptions to both cases were frequently noted. Various combinations of normal, mosaic, leaf-roll, and curly-dwarf plants were obtained from the several tubers of the same plant, and even from the several eyes of the same tuber.

The observations recorded led to the following general conclusions having a practical bearing on seed-potato selection: Normal foliage and high yield is not a guaranty of production in the progeny of the following season, as degeneration may occur quite suddenly. It is unsafe to select seed potatoes from a field con-

taining many degenerate plants, as even the normal plants in such a field may produce worthless progeny. Mosaic is transmitted through the seed and, owing to the difficulty of diagnosis, threatens to become an important factor in seed-potato production. In view of these observations it is doubtful if any method of selection can entirely prevent the degeneration of potato varieties under certain conditions due to the "running out" of the seed.

Some disappointing seed potatoes, F. H. HALL (*New York State Sta. Bul.* 422, popular ed. (1916), pp. 8, figs. 3).—This is a popular edition of the above.

Potatoes, C. A. ZAVITZ (*Ontario Dept. Agr. Bul.* 239 (1916), pp. 88, figs. 28).—This bulletin is a popular discussion of the production of potatoes in the Province of Ontario, including cultural methods, varieties, fungus diseases, insect pests, etc.

Correlative characters of the rice plant, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 9 (1916), No. 2, pp. 74-119).—In a study of rice varieties grown on the lowlands of the Philippines a great quantity of data was collected in correlation studies made in an effort to determine the relative values of the most apparent characters, especially in their relation to the period required by a variety to reproduce itself and to the degree of reproduction. Numerous character correlations were studied and the data are given in tabular form and discussed in detail. Some of the most striking results were as follows:

The length of the growing period of rice, if not less than 120 nor more than 180 days, has no appreciable effect on yield. Extra early maturity is to be had at the expense of yield. Late maturity is conducive to loss through disease, insects, etc. A variety that tillers freely produces more grain per hectare than one that does not; but when rice is transplanted tillering can be largely regulated by the number of plants set in the hill. Tillering, the number of grains per panicle, and grain size are compensating characters. The long period of development in the rice plant permits of environmental influences not met with in such plants as oats or barley. It appears that the medium characteristics, and not the extremes, result in the highest consistent yields.

The weight of rice grains, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 4, pp. 289-291).—The weights of seed from three different sections of the panicle for 58 varieties of Philippine rice are reported.

An early reference to Philippine rice varieties, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 4, pp. 292, 293).—This is a brief account of some early descriptions of Philippine rice varieties.

A Philippine wild rice, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 4, pp. 294, 295, pl. 1).—This is a description of a Philippine rice identified as *Oryza manilensis*.

The causes of low yields of rice in the Philippines, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 4, pp. 262-272, pls. 4).—A number of factors that tend to decrease the yield of rice in the Philippines are discussed and recommendations made for overcoming them. The most important factors are considered to be (1) lack of irrigation essential to the successful production of the varieties grown, (2) lack of uniformity in varieties, and (3) lack of the proper cultural methods.

Methods used to improve rice culture in the Philippines, H. O. JACOBSON (*Philippine Agr. Rev.* [English Ed.], 8 (1915), No. 3, pp. 190-206, pls. 3).—This article classifies the rice varieties in the Philippines as upland and lowland, and describes the cultural characteristics of each group. Cooperative methods and station methods for variety tests are described, together with extension methods employed to acquaint the rice farmers with the improved varieties and methods of cultivation.

The rate of sowing nursery beds; the age of seedlings when transplanted; the influence of each, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.]*, 8 (1915), No. 4, pp. 273-279).—Some notes are given on studies relating to the rate of seeding rice in the nursery and the age of seedlings when transplanted. One cabán (2.13 bu.) is recommended for each 1/20-hectare (0.12 of an acre) seed bed. From 30 to 35 days is regarded as the most suitable age at which to transplant varieties maturing within 150 days, although this will probably vary with individual varieties.

Observations on the influence of area per plant on yield of grain in rice culture, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.]*, 8 (1915), No. 4, pp. 252-261).—This article gives the results of a number of tests with three widely differing varieties to determine the effect upon yield of different spacings of rice plants.

The maturing period of rice was not affected by variations in spacing the hills. It is concluded that under intensive cultural conditions the proper spacing must be determined for each variety, as well as the number of seedlings per hill. One seedling per hill, provided with 100 sq. cm., evidently had ample space and could not utilize a greater area. As a general recommendation, 4 seedlings set in hills 20 by 20 cm. proved practical and beneficial. Furthermore, it is pointed out that some such definite scheme of planting would result in a great saving of seed.

Errors in rice fertilizer experiments, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.]*, 8 (1915), No. 4, pp. 280-282).—This article is a criticism of some fertilizer experiments with rice, pointing out errors in the management, reasoning, and conclusions.

Consumption of rice in the Philippine Islands, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.]*, 8 (1915), No. 4, pp. 283-288).—This article is a brief discussion of the production and consumption of rice in the Philippines since 1909. It is pointed out that there is no tendency toward lessened consumption of rice by the human population.

Some observations on Chinese rice culture, H. O. JACOBSON (*Philippine Agr. Rev. [English Ed.]*, 8 (1915), No. 4, pp. 296-302).—This article consists of general observations made on rice culture in China.

Rye culture experiments with diminishing seeding and increasing nitrogen fertilization at Pentkowo, BIELER (*Illus. Landw. Ztg.*, 35 (1915), No. 101, pp. 654, 655).—Comparisons were made in seeding different amounts of the same variety and different varieties of rye. Later these experiments were extended to include a comparison of varying amounts of nitrogenous fertilizer and different drill widths in sowing the seed. Some work has also been done in regard to the date of seeding.

The results up to 1915 indicated that rye sown at the rate of 30 lbs. per morgen (48 lbs. per acre), in rows 8 in. apart and with 30 lbs. of nitrogen in sodium nitrate gave the highest yields.

Triple-seeded spikelets in sorghum, A. B. CRON (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 4, pp. 237, 238, pl. 1).—This is a report of an abnormality in inflorescence of sorghums in the F<sub>2</sub> progeny of a dwarf feterita hybrid at Amarillo, Tex., in 1915. Several triple-seeded spikelets and a larger number of twin-seeded spikelets in two of the panicles were the unusual characters.

Soy-bean products and their uses, C. B. WILLIAMS (*North Carolina Sta. Circ.* 34 (1916), pp. 7, fig. 1).—This is a general discussion of the commercial uses of soy beans, especially as applied to southern conditions. The extraction of the oil in this country and abroad is briefly described, together with statistics relating to soy-bean oil importations for the five-year period ending with 1916, and for the year of 1916. The use of soy-bean meal as a stock feed and

fertilizer and of the beans and their by-products for human consumption is discussed. It is estimated that from 1 ton of soy beans 1,650 lbs. of meal and 32 gal. of oil can be obtained, leaving a waste composed of trash and moisture of 120 lbs.

[Cultural experiments with different varieties of sugar beets], O. FALLADA (*Österr. Ungar. Ztschr. Zuckerindus., u. Landw., 44* (1915), No. 6, pp. 483-503).—This article reports the results of cultural experiments with five varieties of sugar beets, viz: Dippe, Zapotil, Schreiber, Dobrowitz, and Rabbethge & Giesecke, Dobrowitz being used as a basis of comparison. The experiments were conducted at four experiment stations, and the meteorological and cultural conditions at each station are tabulated and discussed.

Experiments in transplanting sugar beets, F. J. PRITCHARD and L. E. LONGLEY (*Jour. Amer. Soc. Agron., 8* (1916), No. 2, pp. 106-110, pl. 1).—This article gives the results of some experiments in transplanting sugar beets with a view to eliminating the expense of thinning. The experiments were planned to determine two points: (1) The relation of the length and size of the seedling at the time of transplanting to the branching of the mature beet; and (2) the influence of the composition of the seed bed on the length, shape, and amount of root branching. The following results were noted:

By transplanting roots from 8 to 12 in. in length a nearly perfect stand of beets was obtained. Roots from 2½ to 5 in. long remained short and branched excessively, although they grew larger than beets started from seed and thinned. A mixture of ¾ sand and ¼ loam produced the longest, least branched, and best shaped roots, although fairly good roots were obtained in a mixture of half and half. The experiments as a whole indicated the possibilities of transplanting sugar beets economically, especially where the roots can be set by means of a machine.

Fertilizing of sugar beets, GERLACH (*Illus. Landw. Ztg., 36* (1916), No. 22, p. 157).—This article gives the results of some experiments with different amounts of stable manure and commercial fertilizers, both when used alone and together.

In the manure tests the highest returns were obtained from the use of a combination of stable manure and commercial fertilizers. In the commercial fertilizer tests the highest yields were obtained from the use of nitrogenous fertilizers. Recommendations are made for fertilizer treatments based on the results obtained in the experiments.

History of cane varieties in the Philippines, C. W. HINES (*Philippine Agr. Rev. [English Ed.], 8* (1915), No. 3, pp. 152-168, pls. 4).—A brief history of the production of sugar cane in the Philippines is given. A number of foreign varieties of cane introduced into the Philippines are described briefly, together with a few of the so-called "native" varieties. Field and laboratory tests for the purpose of determining the most profitable varieties for that territory are noted.

Tobacco growing in Ireland (*Dept. Agr. and Tech. Instr. Ireland Jour., 16* (1916), No. 3, pp. 404-410).—This article is a brief discussion of the tobacco experiments conducted during 1915, and is in the nature of a preliminary report on some more extensive investigations. The general climatic and agricultural conditions pertaining to tobacco culture for the year are discussed.

The origin, characteristics, and quality of Humpback wheat, L. M. THOMAS (*U. S. Dept. Agr. Bul. 478* (1916), pp. 4, pl. 1, fig. 1).—This bulletin is a brief discussion of the origin and characteristics of Humpback wheat as distinguished from the so-called Velvet Chaff, Glyndon Fife, and Bluestem wheats.

Although Humpback yields well and has proved popular in Minnesota and the Dakotas it is discriminated against by the grain trade because of its alleged

inferior milling qualities. The grade rules for northern spring wheats of the Minnesota State grain-inspection specify that it should not be graded higher than No. 3. Milling and baking tests in cooperation with the North Dakota Experiment Station were conducted with single samples of Humpback wheat from the 1908 and 1909 crops and nine samples from the 1910 crop. These samples were all from Minnesota and were compared with samples of Bluestem and Velvet Chaff wheats of the 1910 crop from North Dakota and Minnesota, with results summarized as follows:

*Comparison of results of milling and baking tests of Humpback wheats with other hard red spring wheats.*

Kind and source of sample.	Yield of straight flour.	Volume of loaf.		Absorption (water used per 100 gm. of flour).	Color of crumb.	Crude protein (N × 5.7).	
		Per 340 gm. of flour.	Per 100 gm. of flour.			In flour.	In wheat.
Humpback wheats from—	<i>P. ct.</i>	<i>Cc.</i>	<i>Cc.</i>	<i>Cc.</i>	<i>Score.</i>	<i>P. ct.</i>	<i>P. ct.</i>
Hoffman, Minn., crop of 1910.....	69.8	2,176	640	50.5	94.8	14.19	14.95
Kensington, Minn., crop of 1910.....	72.9	2,105	619	49.0	95.5	13.23	13.59
Both Hoffman and Kensington, crop of 1910.....	71.2	2,145	531	49.8	95.1	13.76	14.35
Eight samples of Bluestem wheat from North Dakota and Minnesota, crop of 1910.....	69.2	2,430	715	52.1	97.1	12.59	13.40
Seventeen samples of Velvet Chaff wheat, grown in North Dakota, 1910.....	66.9	2,428	713	52.4	99.0	13.37	14.52

Although Humpback evidently excels the smaller grain varieties in yield of flour, its volume of loaf, absorption, and color of crumb are below the standard. The rather high percentage of crude protein in the wheat and flour, coupled with low "baking strength," marks a point of resemblance between Humpback and the durum wheats.

**Variations in the plants from the same head of wheat, A. J. EWART** (*Jour. Dept. Agr. Victoria, 14 (1916), No. 3, pp. 168, 169, fig. 1*).—This article gives the results of some experiments with wheat suggested by work conducted at Rutherglen, Victoria, and previously noted (*E. S. R., 36, p. 440*). The experiments were planned to obtain further evidence upon the variations in the fertility and vigor of individual grains from different parts of the wheat spike. It was found that germination was most rapid in the grains of the sixth row from the top and that the average rate of germination decreased toward the base and apex of the head.

**An effective head thrasher, W. E. HANGER** (*Jour. Amer. Soc. Agron., 8 (1916), No. 4, pp. 267, 268, pl. 1, fig. 1*).—A head thrasher, constructed at the Maryland Experiment Station, to be used in thrashing wheat or oats in variety tests is described.

**Agricultural seed.**—Concerning weeds and weed seeds, G. P. BURNS and A. K. PEITERTSEN (*Vermont Sta. Bul. 200 (1916), pp. 3-79, figs. 52*).—Pages 5-60 of this bulletin include a discussion of the Vermont seed inspection law and a report of the results of the 1916 seed inspection. Pages 60-69 contain a discussion of weeds, their nature and control, together with illustrations and brief descriptions of 52 weeds commonly found in agricultural seed.

**The use of sulphuric acid in combating weeds infesting wheat, A. MORETINI** (*Staz. Sper. Agr. Ital., 48 (1915), No. 10-11, pp. 693-716*).—According to the results of experiments here reported, the use of sulphuric acid at a strength of 66° B. in a solution of 10 per cent by volume and at the rate of 1,000 liters per hectare (about 107 gal. per acre), was of medium efficiency in combating

the greater portion of the weeds infesting wheat fields, but in most cases increased the yield sufficiently to compensate for the expense of the treatment. Where grain was sown in rows it was found better to hoe or cultivate, but where the crop was sown broadcast and the weeds were numerous the treatment with sulphuric acid solution was preferable. The treatment was not useful when the dominant weed species belonged to the Gramineæ, Liliacæ, or other families equally resistant to the action of dilute sulphuric acid.

It was not found that the sulphuric acid treatment is efficient in controlling foot rot of wheat.

Ferrous sulphate control of hedge mustard and wild mustard in Bavaria, 1904-1915, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 14 (1916), No. 2, pp. 13-16, fig. 1*).—This article discusses the use in Bavaria of spraying machinery in the control of the wild mustards with ferrous sulphate.

Ragwort, P. M'GOVERN (*Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 3, pp. 411-417*).—This article deals with the life history and eradication of ragwort (*Senecio jacobæa*) in Ireland. This weed is described as a biennial, propagated only by seed.

## HORTICULTURE.

What, where, when, and how to plant, E. E. BOHLENDER (*Tippecanoe City, Ohio: [Author], 1914, 2. ed., rev., pp. 36, figs. 74*).—A concise manual of information dealing with the culture of berry plants, roses, shrubs, evergreens, vines, and perennials.

Round the year in the garden, H. H. THOMAS (*London and New York: Cassell & Co., Ltd., 1916, pp. XII+275, pls. 76*).—A popular treatise on gardening dealing with the principal flowers, fruits, and vegetables of the various seasons and indicating the chief garden work to be done each month.

The home vegetable garden, C. W. WAID (*Mich. Agr. Col., Ext. Div. Bul. 4 (1916), pp. 35, figs. 10*).—A popular cultural treatise dealing with the farmer's garden, the suburban garden, and the city garden.

Growing seeds for the world, A. KRUEH (*Gard. Mag. [N. Y.], 24 (1916), No. 5, pp. 164-167, figs. 11*).—A popular historical account of the American garden seed industry.

Nitrate of soda spray for fruit bearing, W. H. VOLCH (*Pacific Rural Press, 93 (1917), No. 3, p. 72*).—Popular suggestions on the spraying of dormant fruit trees with nitrate of soda, based on investigations conducted by the author in cooperation with Ballard (E. S. R., 30, p. 640).

Results from spraying in Nova Scotia, G. E. SANDERS and W. H. BRITAIN (*Canada Dept. Agr., Ent. Branch Circ. 7 (1916), pp. 11, pl. 1*).—In this circular the authors present some actual results obtained by owners spraying for profit in their own orchards in the Annapolis Valley, Nova Scotia. The data are discussed under the general headings of increase in quality of apples due to spraying, increase in quantity of apples due to continued spraying, economy in handling clean fruit, and profits in spraying.

The cost of spraying, F. I. ODELL (*Fruit Grower, 28 (1917), No. 1, pp. 3, 27, fig. 1*).—An analysis is given of spraying expenses in some apple orchards in southern Indiana, including tables showing the labor, materials, and cost for spraying one acre of a 30-year-old orchard in 1915, and the maintenance spraying expense for 20 acres for an 8-year period.

The apple as affected by varying degrees of dormant and seasonal pruning, W. H. ALDERMAN and E. C. AUCHTER (*West Virginia Sta. Bul. 158 (1916), pp. 3-56, figs. 22*).—A preliminary report of a pruning experiment covering a period of four years and embracing 366 apple trees of various ages. Study has been

made of the effects on vigor and fruitfulness of various degrees of dormant pruning, summer pruning at different times, and combinations of dormant and summer pruning. The work of other investigators is reviewed and a bibliography of related literature appended.

The results of the pruning work as a whole are in accord with those previously reported by the senior author (E. S. R., 35, p. 142). Although heavy annual dormant pruning has resulted in stronger terminal growth, the gain in total length of growth and in increase in trunk diameter has been less than with lightly pruned trees. Heavy dormant pruning appears to be primarily of value for developing a frame work during the first two or three years of the tree's life and for stimulating fruit production in middle-aged trees that are only in a fair state of vigor. As previously noted all classes of summer pruning have been inferior to dormant pruning.

The authors have also conducted experiments to determine the effects of ringing on the growth and fruitfulness of apple trees. Ringing of trees caused heavy crop production the season following the operation but so impaired the vigor that no crop was produced the second or third years, and at least three seasons were required to restore the tree to normal conditions.

**Apples: Production estimates and important commercial districts and varieties, H. P. GOULD and F. ANDREWS** (*U. S. Dept. Agr. Bul. 485 (1917), pp. 48, figs. 16*).—A statistical study of the apple industry of the United States containing estimates relative to the production and distribution of the principal varieties in the country as a whole and in the individual States, including also an outline of the distribution of the apple industry in each State and the varieties grown. Estimates are also given of the proportion of early and late apples produced in each State and of the annual production of apples as a whole in the United States from 1890 to 1916, inclusive. A portion of the data have been previously noted (E. S. R., 32, p. 438).

**Preliminary observations on the ripening of Bartlett pears, W. V. CRUESS and P. M. STONE** (*Mo. Bul. Com. Hort. Cal., 5 (1916), No. 12, pp. 425-429*).—Data are given on some preliminary tests conducted at the California Experiment Station to ascertain whether the proper time for picking pears to be shipped may be determined by a simple chemical test. The results thus far secured indicate that a minimum size may be of more value than a chemical test in deciding the time of picking.

**Navel persimmons, J. E. CORR** (*Cal. Citrogr., 2 (1916), No. 3, p. 9, fig. 1*).—Some Japanese persimmons observed in California that have a small secondary fruit included within the primary fruit are here illustrated and described.

**The common honeybee as an agent in prune pollination, A. H. HENDRICKSON** (*California Sta. Bul. 274 (1916), pp. 127-132, figs. 2*).—During the past three years the station has been conducting pollination studies with plums and prunes in the Santa Clara Valley. This bulletin comprises a progress report on that part of the project dealing with the honeybee as a factor in prune pollination.

Because of the conflicting reports of the value of interplanting such varieties as the French prune and the Imperial prune, and also because of a noticeable lack of bees and other insects in the prune orchards of the valley during the blooming period, an experiment was planned in which a tent of white mosquito bar was placed over a pair of adjoining French and Imperial prune trees as nearly as possible of the same age and size. A hive of honeybees was kept in this tent throughout the blooming period. A similar tent inclosed a pair of French and Imperial prune trees, from which bees and other insects were excluded throughout the blooming period. Observations were made on the set of fruit under these tents and also on trees of these varieties exposed to normal conditions.

The honeybees seemed to prefer the flowers of the French prune and seemed to devote most of their attention to this variety. As a result, the French prune tree exposed to the bees set a much heavier crop than that of the best trees exposed to normal conditions, whereas the Imperial prune tree exposed to the bees set only a light crop of fruit. The French prune tree from which bees were excluded set only a very light crop and the Imperial prune tree only a few scattering fruits. The experiment is to be repeated to determine, if possible, why the Imperial prune did not respond to pollination by the bees.

The work thus far conducted indicates that the French prune at least may be aided in setting a satisfactory crop by the presence of a large number of bees in the orchard during the blooming period.

**Inheritance in Vitis**, RASMUSON (*Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 29-34, figs. 4*).—Data are given on character transmission in crosses between a number of selected phylloxera-resistant direct-bearing grapes and grafting stocks.

The results in general show that the trend of variation for some characters at least is the same for crosses between species as between varieties of the same species. Crosses between phylloxera-susceptible species yielded phylloxera-susceptible offspring. Crosses between phylloxera-resistant species gave both susceptible and resistant offspring, with the latter dominant. Immunity to phylloxera was also dominant and susceptibility recessive in the progeny of crosses between susceptible and resistant species.

**Portuguese varieties of vines**, F. DE CASTELLA (*Jour. Dept. Agr. Victoria, 14 (1916), Nos. 7, pp. 398-408; 9, pp. 565-570; 10, pp. 622-628; 11, pp. 673-686; 12, pp. 731-740, figs. 22*).—A descriptive account of the varieties of grapes grown in Portugal for the production of port wine.

**Arsenate of lead in viticulture**, C. F. MUTTELET (*Ann. Palsif., 9 (1916), No. 94-95, pp. 298-301*).—Analyses were made to determine the amounts of lead, copper, and arsenic in the wines, lees, and marcs of grapes sprayed with arsenate of lead after the formation of seeds.

The wines contained only very slight traces of copper and arsenic and no lead. The lees contained per liter 500 mg. (3.5 grains per lb.) of lead, 10 mg. of arsenic, and traces of copper. The marc contained per kilogram of dried product 200 mg. (1.4 grains per pound) of lead, 0.1 mg. of arsenic, and traces of copper. These results indicate that the consumption of wine before the lees are deposited may be dangerous and that the marc should not be fed to stock. Generally speaking, however, the use of arsenical sprays after the seeds are formed does not introduce toxic metals into products of consumption that are prepared with care.

**Varietal standardization**, L. B. SCOTT (*Cal. Citrogr., 2 (1916), No. 3, pp. 8, 9, fig. 1*).—In this paper the author points out the need of varietal standardization for the greater development of our subtropical fruit industries, special attention being given to the citrus fruits, avocado, and olive.

**Four years' experience with budded avocado trees**, J. T. WHEDON (*Cal. Citrogr., 2 (1916), No. 3, p. 7*).—A brief summary of results secured in Orange County, Cal., with 342 avocado trees, including 29 different varieties.

[Cacao experiments, 1914-15], J. DE VERTEUIL (*Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 6, pp. 183-205, pls. 8*).—This report is supplementary to a previous report for 1914-15 (E. S. R., 36, p. 141), and gives the results of manurial and natural yield experiments with cacao on a number of additional estates in Trinidad and Tobago not previously mentioned.

**Bud variation in lemons**, A. D. SHAMEL (*Cal. Citrogr., 2 (1917), No. 4, pp. 6, 7, 16, figs. 3; Jour. Heredity, 8 (1917), No. 2, pp. 75-81, fig. 1*).—A paper on

this subject read before the American Genetic Association in New York City in December, 1916, in which the author points out that recent studies with lemons in California have shown bud variation to take place as in the earlier work with the Washington navel orange (E. S. R., 34, p. 639). The records and observations of the lemon studies are to be published at a later date. The desirability of further systematic investigations of bud variations in citrus fruits grown in other regions and in all other plants propagated vegetatively is pointed out.

Notes on oranges and lemons, H. J. DAVIES (*Dept. Land Rec. and Agr., United Prov. Agra and Oudh, Bul. 38 (1916), pp. 22*).—Cultural notes, with special reference to conditions in India, are given.

How to fertilize olive trees, A. ROLET (*Vie. Agr et Rurale, 6 (1916), No. 53, pp. 474-479, figs. 3*).—Suggestions on fertilizing olive trees, with fertilizer formulas recommended by different authorities, are presented.

Manganese as a cause of the depression of the assimilation of iron by pineapple plants, M. O. JOHNSON (*Jour. Indus. and Engin. Chem., 9 (1917), No. 1, pp. 47-49, fig. 1*).—A summarized account of experiments which will be given in fuller detail in a publication of the Hawaii Experiment Station.

In continuation of the investigations by Wilcox and Kelley (E. S. R., 27, p. 842), showing the detrimental effects of manganese in pineapple soils in Hawaii, the author finds that the manganese of the highly manganiferous soils of the island of Oahu is nearly, if not all, in the dioxid form, and that the toxic effect observed on pineapple plants is due to a depression in the assimilation of iron. Pineapple plants have recovered from the toxic effects of manganese when supplied with iron through the leaves by means of sprays. A commercially successful treatment has been worked out and the profitable utilization of these highly manganiferous soils seems assured.

Soil management in cinchona culture, P. VAN LEERSUM (*Grondbewerking bij de Kinacultuur. Surabaya, Java: Nederland.-Ind. Landb. Synd., 1916, pp. 13*).—A paper introducing themes for discussion at the Dutch India Soil Congress at Djokja, in October, 1916. Some comparative data are given showing the beneficial results of intensive culture in growing cinchona.

The cultivation of belladonna in California, A. SCHNEIDER (*California Sta. Bul. 275 (1916), pp. 135-160, figs. 12*).—This bulletin gives directions for growing belladonna based upon numerous field tests, many of which were on a commercial scale, conducted under the direction of the station. The California and other American cultural experiments with belladonna are summarized and the plant is considered with reference to climatic and soil requirements, seed germination and care of the seedlings, transplanting seedlings and crown cuttings, care of the crop, harvesting, preparation for market, yields, and field enemies of belladonna. Data are also given relative to the alkaloidal yield of belladonna of different ages, together with suggestions for increasing the alkaloidal contents of the plants.

Possibility of the commercial production of lemon-grass oil in the United States, S. C. HOOP (*U. S. Dept. Agr. Bul. 442 (1917), pp. 12, figs. 3*).—This bulletin combines directions for growing lemon grass (*Cymbopogon citratus*) and the production of oil with the results of experiments conducted by the Bureau of Plant Industry in central Florida during the past eight years in which field tests were made with 13 varieties secured from 8 different parts of the world.

Consideration is given to the soil and climatic requirements of lemon grass, propagation, fertilizers and cultivation, harvesting, distillation, varieties, factors affecting the yield and citral content of lemon-grass oil, solubility of lemon-grass oil in alcohol, and commercial possibilities. The experiments as a whole indicate that the production of lemon-grass oil would not be profitable if all

overhead charges for the distillation plant were placed against this crop alone. It is believed, however, that if grown in connection with other volatile oil plants, thus prolonging the distilling season, this crop will yield returns comparing favorably with other crops grown on the same type of land.

What science has done and will do for floriculture, E. A. WHITE (*Gard. Chron. Amer.*, 21 (1917), No. 1, pp. 11-14).—An abstract of a lecture in which the author reviews some of the scientific contributions to the development of ornamental plant production.

## FORESTRY.

Eighth annual report of the state forester.—Forestry in Vermont, A. F. HAWES (*Ann. Rpt. State Forester Vt.*, 8 (1916), pp. 43, pls. 3).—This report outlines forest planting operations in the State and gives an account of activities at the state nurseries and on the various state forests, including data on the white pine blister rust inspection for 1916 and a financial statement for the year. A report on forest fires for 1915 by R. M. Ross and a note by B. A. Chandler on the assistance rendered to private owners in the close utilization of forests are also included.

Progress report of the Forest Research Institute for the year 1915-16, B. B. OSMASTON (*Rpt. Forest Research Inst. [Dehra Dun], 1915-16, pp. 21*).—A brief progress report of the investigation and research work of the institute dealing with silviculture and working plans and with forest botany, economy, zoology, and chemistry. Lists of forest publications issued since the establishment of the Forest Research Institute are appended.

The trees of Vermont, G. P. BURNS and C. H. OTIS (*Vermont Sta. Bul.* 194 (1916), pp. 3-244, pls. 9, figs. 507).—A classification with popular descriptions of the trees of Vermont, and comprising a revision of Bulletin 73 of the Vermont Station (E. S. R., 12, p. 153) in which considerable material published by Otis elsewhere (E. S. R., 29, p. 43) has been adapted in somewhat revised form to Vermont conditions. The bulletin is intended primarily for the use of pupils in public schools and of persons not especially trained in botany.

The vegetation of the New Jersey pine barrens, J. W. HARSHBERGER (*Philadelphia: Christopher Sower Co.*, 1916, pp. XI+329 pls. 2, figs. 283).—A descriptive account of the pine-barren vegetation of the coastal plain of New Jersey from the phytogeographic and ecologic aspects. The subject matter is based upon observations and research work which have been in progress for a period of at least 25 years.

The sandalwoods of Hawaii.—A revision of the Hawaiian species of the genus *Santalum*, J. F. ROCK (*Bd. Comrs. Agr. and Forestry Hawaii, Bot. Bul.* 3 (1916), pp. 43, figs. 13).—A key with botanical descriptions is given of nine species and two varieties of sandalwood, native to Hawaii.

The conifers and taxads of Japan, E. H. WILSON (*Pubs. Arnold Arboretum No. 8* (1916), pp. XI+91, pls. 59).—A descriptive account with illustrations and a full synonymy of different species and varieties of the conifers and taxads of Japan, including references to the principal literature on the subject.

Indian timbers used in engineering construction, R. S. PEARSON (*Trans. Internat. Engin. Cong., 1915, Materials for Engin. Construct.*, pp. 15).—A paper presented at the International Engineering Congress at San Francisco in September, 1915. It briefly describes the principal timber species of India with reference to their distribution, growth, physical and mechanical properties, uses, yield, and prices; summarizes what is being done to maintain the supply of timber; and reviews the economic position of the timber trade in India.

Experimental notes on the bitter oak, E. FERRARI (*Bol. Quind. Soc. Agr. Ital.*, 21 (1916), No. 24, pp. 678-681).—The author calls attention to the importance of securing data on the growth of Italian trees, and presents diameter, height, and volume measurements of 22 bitter oak trees ranging in age from 39 to 97 years.

Gutta-percha, B. H. F. BARNARD (*Agr. Bul. Fed. Malay States*, 5 (1916), No. 2, pp. 25-37).—An account of gutta-percha-yielding trees with reference to their botany, general distribution, and distribution in the Federated Malay States, including also considerations relative to methods of extracting gutta-percha, yield, cost of tapping, cultivation, improvement of natural gutta-percha forests, and pests. Tabular data are given showing the yield of clean gutta from a number of trees that have been tapped four times during the period 1909 to 1915.

### DISEASES OF PLANTS.

Laboratory outlines in plant pathology, H. H. WIETZEL, L. R. HESLER, C. T. GREGORY, and W. H. RANKIN (*Ithaca, N. Y.: Authors, 1916, pp. 207*).—The outlines given are those used at Cornell University, no attempt having been made to adapt them for use at other institutions. Instructors are expected to select materials suitable for their courses. The sequence of procedure is essentially the same in all exercises, and its mastery should result in the student's acquiring habits of orderly and logical investigation. The authors express the hope that the grouping of the diseases studied will direct attention from the dominance of systematic mycology and turn it to the more logical classification and study of plant diseases based on pathological phenomena.

Diseases of cultivated plants and trees, G. MASSEE (*New York: The Macmillan Co., 1915, 2. ed., pp. XII+602+16, figs. 173*).—The new matter contained in this book is embraced in a supplement to the original edition (*E. S. R.*, 24, p. 44). Descriptions are given of 20 or more diseases that have made their appearance or assumed economic importance since the earlier publication.

Report of committee on fungus diseases, T. F. MANNS (*Trans. Peninsula Hort. Soc. [Del.]*, 28 (1915), pp. 52-63).—This is a condensed account of insect injury during 1914, also of plant diseases and of measures for their control, including a plant disease survey, the results of which are discussed.

Report of committee on fungus diseases, T. F. MANNS (*Trans. Peninsula Hort. Soc. [Del.]*, 29 (1916), pp. 58-64).—Like the above report for the previous year, this deals partly with the prevalence, progress, and control of plant diseases in other sections of the country, but more particularly with diseases and contributing or opposing factors and results in and near Delaware. Some prevalent diseases of the season are briefly reported on in connection with the plants affected thereby.

Cooperation in the investigation and control of plant diseases, K. F. KELLERMAN (*Abs. in Mem. N. Y. Bot. Gard.*, 6 (1916), p. 517).—This is an argument for closer cooperation between specialists studying plant diseases, on the one hand, and Federal, State, and local officials on the other, in order to secure quicker diffusion of knowledge regarding plant diseases and earlier and more effective employment of agencies for their prevention or control.

[Plant diseases in Barbados], J. R. BOVELL and J. S. DASH (*Rpt. Dept. Agr. Barbados, 1914-15, pp. 20-25, 43, 44*).—This portion of the annual report includes, among other data presented and discussed, a tabular account of the proportion of disease in the cotton hybrids under cultivation during 1910 to 1915 and a similar account of the prevalence of fungus diseases in cotton from the

experimental plats at Sæmmervale during the seasons 1913-14 and 1914-15. Descriptive and other data regarding the cotton varieties employed are included.

The root disease of sugar cane, due to *Marasmius sacchari*, was noted on one estate in 1914, but the use of resistant varieties has in recent years helped to lessen the amount of trouble from this source. *Thielaviopsis paradoxa* (*T. ethacetica*) was troublesome on some estates, experiment proving the necessity of properly making up the Bordeaux mixture for use in this connection. *Colletotrichum falcatum* was not severe during the season.

Late cottons were badly affected with black arm, angular leaf spot, and bacterial boll disease, all due to *Bacterium malvaccarum*. Losses from anthracnose (*Glomerella gossypii*) were comparatively slight.

The Gloeosporium dieback of cassava was again prevalent in some districts, and some plants at Codrington suffered considerably from a bacterial leaf disease. Yams were affected by a blackening fungus on the stems and leaves, the spore measurements of which agree closely with those of *G. pestis*.

Grapes affected with anthracnose (*G. ampelophagum*) were noted, the stems also being attacked. Leaves of grape growing in an unsuitable situation showed the presence of vine rust (*Uredo vitis*), also of a species of *Cercospora*, possibly *C. viticola*.

Young mango trees were attacked by *G. mangiferae*, which blackened the shoots and portions of the young stems. Sorghum leaves showing rust were found to bear *Puccinia purpurea* and the rust parasite *Darlucia filum*. A leaf spot associated with *Glaosporium* sp. was observed to cause considerable injury to *Pithecolobium unguis-cati*. Some palms of the genus *Phœnix* were found to be affected with *Graphiola phœnicis*.

Annual report for 1915 of the botanist, R. H. BIFFEN (*Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 309-313).—This report deals with tests of seeds; identification of weeds, grasses, and cereals; rapelike sports among swedes and cryptogamic plant diseases, these last including potato-leaf curl and tuber wet rot; a rust and a bacterial disease of mangold; club root of swedes and cabbage; mildew in oats, vegetable marrow, and parsnips; blindness in barley and wheat; wheat bunt; alfalfa sickness; mildew on apple, peach, and gooseberry; pear scab; apple canker; plum silver leaf; Botrytis on lettuce; and minor diseases of ornamental plants.

*Leptosphaeria culmifraga* is claimed to produce brittleness of wheat stems near the ground level. *Sporidesmium solani varians* appears to be somewhat common, causing a leaf spot of early potatoes, but to be controllable by the timely use of Bordeaux mixture.

Hydrogen ion concentration and natural immunity in plants, R. J. WAGNER (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1916), No. 24-25, pp. 708-719, figs. 7).—A preliminary account is given of studies with *Sinapis alba*, *Brassica olerifera*, *Semperivum hausmannii*, and *Solanum tuberosum*.

It is stated that the variation of hydrogen ion concentration in plant tissues is a phenomenon of reaction to the injection of pathogenic bacteria. The course and end results are related to the susceptibility of the plant in question and to the character of the disease as acute or chronic.

Crown gall or plant cancer, C. O. SMITH (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 6, pp. 201-211, figs. 3).—This is a somewhat general discussion of the now almost world-wide crown gall organism, *Bacterium tumefaciens*, and its degree of attack and other relations to the large number of plants which it can infect either naturally or artificially.

It is believed that the soils of California are often naturally infected with the crown gall organism, especially in case of those that were formerly wooded

or used for the growing of stone fruits. The organism is thought to be entirely a wound parasite.

Resistant stock is regarded as the most hopeful means of control, several varieties of plum being on trial in this connection. Rigid inspection before planting in the fall and again after the active spring growth sets in is regarded as very important. Tree surgery is considered as on the whole so uncertain and unsatisfactory as to be impracticable.

**North American species of Allodus**, C. R. ORTON (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 173-208).—This account deals with the genetic and host relationships, life history, and classification of the genus *Allodus*, the hosts of which are said to number seven monocotyledonous and 40 dicotyledonous species distributed among 21 families representing 14 orders.

Some species of *Nummularia* common in Indiana, C. E. O'NEAL (*Proc. Ind. Acad. Sci.*, 1914, pp. 235-249, figs. 15).—Results are given of the examination of five species of *Nummularia* found at points in Indiana and elsewhere, only one of these, *N. discreta*, being regarded as of much economic importance.

The genus *Rosellinia* in Indiana, G. B. RAMSEY (*Proc. Ind. Acad. Sci.*, 1914, pp. 251-265, figs. 9).—A brief account is included of eight species of *Rosellinia* said to be destructive to living plants mentioned in this connection.

**Correlation of certain long-cycled and short-cycled rusts**, H. C. TRAVELBEE (*Proc. Ind. Acad. Sci.*, 1914, pp. 231-234).—The author has made a study of several species of *Puccinia* and furnishes a short list of combinations which are regarded as good correlations. It is thought that the possibilities of correlation studies are very numerous and that the practical application of the knowledge so gained will be made along the lines of culture work, especially in forecasting the alternate host plants of unconnected aecial or telial forms.

**Continuous rust propagation without sexual reproduction**, C. A. LUDWIG (*Proc. Ind. Acad. Sci.*, 1914, pp. 219-230).—The author, presenting data obtained largely from contributions of other investigators, concludes that a good many rusts can pass the winter and propagate themselves for a long time, if not indefinitely, maintaining a high degree of vigor without employing the sexual mode of reproduction.

**Cereal diseases and pests**, E. RIEHM (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1915), No. 14-16, pp. 385-407).—This is a review of contributions by various authors during 1914 regarding injuries done to cereal crops by animal and vegetable parasites and by agencies not parasitic in character, about 124 titles being listed.

**Cereal rusts in subtropical South America**, G. GASSNER (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1916), No. 9-13, pp. 305-381).—This is a study of the more common rusts affecting economic grains in the La Plata region at ten developmental stages of the plants, as carried out at periods during 1907 to 1910. The account includes also a discussion of climatic conditions in this region, the observed forms and specializations of the rusts, and their relations to particular varieties of the different grains.

The dependence of cereal rusts upon the development stage of the host plant and upon external factors, G. GASSNER (*Centbl. Bakt. [etc.]*, 2. Abt., 44 (1915), No. 17-23, pp. 512-617).—This is a further report on the study above noted. It deals in considerable detail with the direct and indirect influence of climate, soil, and other factors as related to rust attack, and with the significance in this connection of developmental stages of different portions of the plants.

**Oat smut in Indiana**, F. J. PIPAL (*Proc. Ind. Acad. Sci.*, 1914, pp. 191-196).—While oat plants from fields of different counties in Indiana, sown with seed that had not been treated, showed proportions ranging from 11 to over 20 per cent of smut infection, the proportion was reduced to an average of about 0.3 per cent

by the use of the formaldehyde treatment, which is shown to be both simple and inexpensive. One pint of formaldehyde is added to 50 gal. of water, and the seed are thoroughly moistened by constant stirring, spread out to dry, and sown as soon as they will run through the drill, or dried more thoroughly if sowing is to be postponed.

**Leaf smut of timothy, G. A. OSNER** (*New York Cornell Sta. Bul.* 381 (1916), pp. 187-230 pl. 1, figs. 14).—The leaf smut of timothy due to *Ustilago striiformis*, which also occurs on a large number of other grasses, is described. This fungus is of economic importance through its reduction of the yield of hay and of seed. The symptoms of the disease, its etiology, and pathology are described, after which an account is given of the effect of seed treatment by means of formaldehyde, hot water, and copper sulphate solutions. The results, while not conclusive, are considered to point strongly to the probability that the disease may be controlled by treating the seed with hot water.

A bibliography is appended.

**Plant diseases affecting alfalfa, L. E. MELCHERS** (*Quart. Rpt. Kans. Bd. Agr.*, 35 (1916), No. 138, pp. 339-353, figs. 19).—Brief popular accounts are given of a number of diseases occurring on alfalfa in Kansas, the diseases being grouped according to their causes as parasitic or nonparasitic. In the first group the author describes dodder, leaf rust, leaf spots, bacterial stem blight, violet root rot, downy mildew, and a *Phoma* stem disease. In the second group accounts are given of a stem-cracking disease and yellow top of alfalfa.

In addition to the diseases enumerated, brief accounts are given of brown root rot, crown wart, and root knot, parasitic diseases which are not yet known to occur in the State.

**Alfalfa crown wart in the western United States, R. MCKEE** (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 4, pp. 244-246).—Discussing the life history and distribution of *Urophlyctis alfalfæ*, the author states that the question whether or not this fungus is endemic in the western United States has not yet been settled. Alfalfa plants grown in 1910 from seed imported from Peru, where the disease is known to exist, had considerable crown wart in 1914. Plants, apparently healthy, of *Medicago falcata*, originating at Highmore, S. Dak., and grown in 1914 and 1915 on ground that had never before grown alfalfa, showed a few well-developed galls of the crown wart. In this case it is thought that the farm implements may have carried the infection from other plants at the station.

Observations made in the Sacramento Valley are considered to show that the crown wart decreases the yield of hay and shortens the life of the plants. It occurs on light, sandy, and peat soils almost or quite as abundantly as on heavier soils, but is more abundant on overflowed than on higher lands. In this region the fungus is in its active stage of growth during the latter part of winter, spring, and early summer, the galls drying and disintegrating early in July. The disease is thought to be more abundant and widespread in the western United States than is commonly supposed.

**A new disease of beets in northern France, E. MIÈGE** (*Vie Agr. et Rurale*, 5 (1915), No. 19, p. 341, fig. 1).—A description is given of a beet disease which appeared in 1915 in northern France. It is characterized by orange-colored spots, irregular swellings, and distortion of the foliage. The old leaves are the first to show alteration, which is associated with more or less retardation and abnormality of development in other parts of the plant. The trouble is thought to be due to physiological causes.

**Is cucumber mosaic carried by seed? J. A. McCLINTOCK** (*Science, n. ser.*, 44 (1916), No. 1144, pp. 786, 787).—The author presents evidence which seems to show that the cucumber mosaic, or white pickle, disease is carried by seed.

Peanut mosaic, J. A. McCLINTOCK (*Science, n. ser., 45 (1917), No. 1150, pp. 47, 48*).—The author reports having observed in a peanut field a plant one shoot of which bore mottled leaves. This plant was transferred to a greenhouse, and at the same time mature pods from it were planted to determine whether the mosaic would be transmitted, but thus far there is no indication that the trouble is carried by the seed. Attempts to produce mosaic by inoculation, as well as other tests to determine its infectious nature, have given negative results.

Fungus parasites of the pigeon pea, E. RANGEL (*Lavoura; Bol. Soc. Nac. Agr. [Brazil], 18 (1914), No. 1-4, pp. 5-18, pls. 3*).—This information, which has been noted previously from another source (*E. S. R., 34, p. 52*), is here given in both Portuguese and French.

A contribution to our knowledge of silver scurf (*Spondylocladium atrovirens*) of the white potato, J. J. TAUBENHAUS (*Mem. N. Y. Bot. Gard., 6 (1916), pp. 549-560, pls. 3*).—It is claimed that *S. atrovirens*, which is carried by seed or soil, is the cause of the disease of white potato known as silver scurf. This fungus is not causally connected with *Phellomyces sclerotiophorus*, which appears to be a saprophyte or very weak parasite. It is stated that the genus *Phellomyces* is not valid, the fungus really belonging to *Colletotrichum*, and *P. sclerotiophorus* being identical with *C. solanicolum* and *Vermicularia atramentaria*. It has accordingly been designated as *C. atramentarium*.

The sweet potato "soil rot" or "pox," a slime mold disease, J. A. ELLIOTT (*Delaware Sta. Bul. 114 (1916), pp. 2-25, figs. 22*).—For several years work has been in progress on the cause and means of control of a disease of sweet potato known as soil rot or pox. The author, in the present publication, gives an account of laboratory studies and field observations of this disease, which he reports is due to a slime mold and not to *Acrocystis batatae*, as previously claimed (*E. S. R., 2, p. 416*). The organism causing the disease is described under the name *Cystospora batata* n. g. and sp., and its life history and cytology are reported at length.

The sweet potato "soil rot" or "pox" organism, J. A. ELLIOTT (*Science, n. ser., 44 (1916), No. 1142, pp. 709, 710*).—A preliminary account is given of the sweet potato soil rot or pox (see above).

Tree wounds and diseases, their prevention and treatment, A. D. WEBSTER (*London: Williams & Norgate, 1916, pp. XX+215, pls. 32, figs. 9*).—This book deals in a general way with the treatment of tree wounds and diseases, the information being based on the author's practical work and observation. The author discusses the management of decaying trees, treatment of hollow trunks, supporting heavy and diseased branches, treatment of injuries from various causes, such as the adverse influence of soil or atmosphere, fungi, insects, etc., the prevention of diseases, and accidents and diseases to which trees are liable, A special chapter is given on fruit trees and their enemies.

Sun scald of fruit trees, a type of winter injury, A. J. MIX (*New York Cornell Sta. Bul. 382 (1916), pp. 235-284, pls. 2, figs. 2*).—A description is given of the winter injury to fruit trees commonly known as sun scald, in which the sun-exposed side of the trunk is affected. Two other types of injury somewhat related to sun scald are crotch injury and crown injury, or crown rot, both of which are discussed in connection with sun scald. In the author's experiments, artificial freezing and thawing at various temperatures were resorted to, their effect on the cambium being noted.

Sun scald injury is considered due to direct freezing to death of tissues through an increased tenderness of the tissue on the sunny side of the trunk in late winter or through a rapid temperature fall which causes the killing of the tissues on the sunny side of the tree at a higher temperature. Both of these

factors may be concerned in the injury. Sun scald is considered to be a late winter injury, as distinguished from crown rot, which is perhaps an early winter injury. Sun scald is, therefore, not induced by late growth or an unripened condition of the tree in the fall, while crown rot is undoubtedly due to this condition.

As a result of experiments, the author claims that a practical method of controlling sun scald is to spray or paint the trunks of the trees with whitewash in the fall or early winter. This method is considered more feasible than shading with boards or otherwise.

**Control of pear scab**, R. E. SMITH (*California Sta. Circ. 157 (1916), pp. 4, figs. 5*).—Suggestions are given for the control of pear scab, plowing under of the dead leaves and two sprayings with Bordeaux mixture as the buds are unfolding being recommended. As an extra precaution a third spraying, with Bordeaux mixture to which lead arsenate has been added for codling moth control, may be given.

**Peach scab and its control**, G. W. KEITT (*U. S. Dept. Agr. Bul. 395 (1917), pp. 66, pls. 6, figs. 6*).—The results of laboratory and field investigations on peach scab, due to *Cladosporium carpophilum*, and its control are given. Peach scab is said to occur in practically every important peach-growing district in the United States east of the Rocky Mountains, and its presence has also been recorded in Canada, Europe, Australia, and South Africa. The characteristics of the disease are given, and the life history of the organism is described.

Inoculation experiments with single spore strains of the fungus from the fruit of the peach and from twigs and leaves gave typical infections in every case, with the exception of the leaf strain inoculated upon the fruit. Scab infection naturally appears shortly prior to the ripening period of the earlier varieties and may continue throughout the season. Primary infection is said to be produced by conidia from overwintered twig lesions. The fungus overwinters in the mycelial stage on living twigs and no evidence has been found of any other type of overwintering that is of practical importance in the life history of the parasite, although it has been shown that the mycelium may survive the winter on fallen fruit and twigs. The varying resistance of different varieties of peaches to scab is pointed out, and as a result of the experiments of the author and others, it is claimed that it may be satisfactorily controlled by spraying with self-boiled lime-sulphur or with finely divided wettable sulphur.

**Grape anthracnose in America**, C. L. SHEAR (*Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 111-117, figs. 4*).—The author states that while grape anthracnose due to *Sphaeceloma ampelinum* has apparently not been found on wild grapevines native to this country, it is known to attack varieties derived from our native species. A resemblance noted between the anthracnose fungus of the grape and that of some species of *Rubus* has suggested the possibility of a close relation or identity of the causal organisms, which is to be investigated.

The unpleasant features of the iron sulphate and sulphuric acid treatment are said to be obviated by the use of the effective combined lime-sulphur and Bordeaux mixture treatment which has been worked out by Hawkins (*E. S. R., 28, p. 649*). This proved to be successful when used in connection with removal of diseased material.

**Studies on *Plasmopara viticola* (downy mildew of grapes)**, C. T. GREGORY (*Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 126-150, figs. 37*).—This is an account of studies by the author and by others on the various phases of development of *P. viticola*, including the pathological histology and physiology and circumstances determining resistance or susceptibility to downy mildew.

Downy mildew on direct bearers, S. OBIEDOFF, J. BAQUERO, and D. V. PEHLIVANOGLU (*Ann. École Nat. Agr. Montpellier, n. ser., 14 (1915), No. 4, pp. 282-322, figs. 2*).—The authors have made very extensive observations regarding the degree of mildew attack on direct bearer vines of several species and numerous varieties in the collection of the School of Agriculture at Montpellier. The results are tabulated and discussed at greater length than in the account previously noted (*E. S. R., 35, p. 352*). It is admitted that no ideal direct producer uniting the comparatively high but not complete resistance shown by American vines with the flavor of product and adaptability characterizing French vines has been found to exist in that collection.

Variations in the resistance of grape to downy mildew, L. RAVAZ and S. OBIEDOFF (*Ann. École Nat. Agr. Montpellier, n. ser., 14 (1915), No. 4, Prog. Agr. et Vit. (Ed. l'Est-Centre), 37 (1916), No. 19, pp. 441-447, figs. 6, pp. 255-263, figs. 6*).—Having observed a more marked attack on grape blooms than on peduncles, the authors made a study of the numbers of stomata, supposedly the only points of invasion by the fungus.

The stomata were found to be more numerous in the case of the more resistant American vines. Stomatal numbers are considered to be unimportant as a factor determining susceptibility to mildew attack, which appears to depend upon conditions within the tissues themselves.

Powdery mildew of grapes and its control in the United States, D. REDDICK and F. E. GLADWIN (*Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 117-125*).—This paper relates mainly to experience during 1911 to 1914 with fungicides differing in form, composition, and mode of application in the grape belt in Chautauqua County, N. Y. The tests with powdered sulphur yielded results which were inconclusive, necessitating their repetition with modifications.

Leaf spots on vines, W. H. DOBSON (*Gard. Chron., 3. ser., 59 (1916), No. 1534, p. 267*).—Discussing in a preliminary note the work of previous experimenters in connection with his own recent work on leaf spot of grapevines, the author concludes that boron in the soil is probably the cause of the disease.

Chlorosis of pineapples induced by manganese and carbonate of lime, P. L. GILE (*Science, n. ser., 44 (1916), No. 1146, pp. 855-857*).—Attention is called to experiments carried out by M. O. Johnson, of the Hawaii Experiment Station, for the control of chlorosis of pineapples on highly manganiferous soils by spraying the leaves with ferrous sulphate. The author points out differences between this form of chlorosis and that described by him in Porto Rico as induced by carbonate of lime (*E. S. R., 26, p. 121*). These differences lead him to believe that the manganese chlorosis may be due in part to a deficiency of iron in the plant caused by the action of manganese in the plant or in the soil, and in part to a direct toxic effect of manganese, while the lime-induced chlorosis is supposedly caused by a lack of iron in the plant due to carbonate of lime's diminishing the availability of iron in the soil. It is stated that these two kinds of chlorosis may be found essentially the same, except for certain secondary effects produced by an undue absorption of manganese.

The causes of unnecessary decay in lemons, R. L. WILLITS (*Mo. Bul. Com. Hort. Cal., 5 (1916), No. 6, pp. 213-216*).—This is a discussion of experiences in the growing, picking, and packing of lemons with reference to losses from diseases due to injury and from infection in the soil. Emphasis is placed on a strict organization of the work with a view to locating and minimizing injury to the fruit.

Overwintering of *Oidium* parasitic on *Photinia serrulata*, V. PEGLION (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), I, No. 5, pp. 341, 342*).—A brief account is given of a fungus described in part which, in the conidial stage here noted as parasitic on *P. serrulata*, presents considerable

analogy with *O. farinosum*. The mycelium appears to winter in the host, adding another example of this adaptive device to those previously noted by others, more recently by Melhus (E. S. R., 34, p. 154).

An *Oidium* mildew on carnations, W. B. MERCER (*Jour. Roy. Hort. Soc.*, 41 (1915), No. 2, pp. 227-229, fig. 1).—A fungus noted in 1914 as causing a mildew on carnations and said to be a member of the Erysiphaceæ has not yet been fully identified.

A spray which is said to control the disease is made up for keeping in stock by mixing 1.75 lbs. of crystallized copper sulphate and 1 qt. of strong ammonia with 2.5 gal. of water. Before using, each pint of this is to be diluted with 8 gal. of water.

Lime-sulphur, though effective as a fungicide, injures the appearance of the plants.

The biology of Uredineæ on Geranium, GINA JACOB (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 44 (1915), No. 17-23, pp. 617-658, figs. 7).—Details of a study are given relating chiefly to the biology of the species of *Puccinia* and *Uromyces* on Geranium and Polygonum.

A new leaf spot of *Viola cucullata*, H. W. ANDERSON (*Proc. Ind. Acad. Sci.*, 1914, pp. 187-190).—A preliminary report is made on a leaf spot of *V. cucullata* believed to be caused by a *Colletotrichum*, not previously noted in this connection, but probably identical with that occurring on *V. rotundifolia*.

The control of damping-off of coniferous seedlings, C. HARTLEY and R. G. PIERCE (*U. S. Dept. Agr. Bul.* 453 (1917), pp. 32, pls. 2, fig. 1).—Accounts are given of experiments for the control of damping-off of coniferous seedlings due to various fungi, among them *Pythium debaryanum*, *Fusarium moniliforme*, and *Corticium vagum solani*.

Experiments for the control of loss due to damping-off are reported from a number of Forest Service nurseries and elsewhere, in which various methods of soil disinfection were tested. Of the many methods tested, treatments with sulphuric acid, copper sulphate, zinc chlorid, and formaldehyde have proved most satisfactory, but the different disinfectants behaved quite differently at different nurseries. On the whole, dilute sulphuric acid has given the best results. Heat disinfection has been only partially effective. In some soils formaldehyde was found to kill dormant seed, while the other chemicals mentioned caused in some nurseries the death of the root tips of the germinating seedlings. Sulphuric acid as a disinfectant has in some cases resulted in a marked increase in the late season growth of pine seedlings.

Parch blight on Douglas fir in the Pacific Northwest, T. T. MUNGER (*Plant World*, 19 (1916), No. 2, pp. 46, 47).—A description is given of an injury to the foliage of Douglas fir trees at points in Oregon and Washington. This appears serious in spring in case of isolated trees of all ages on the eastern edges of groves and is ascribed to exposure of these trees to the drying Chinook winds at the time of the year when they are least able to withstand the parching influence of these winds. The injury is most severe on the so-called coast form of the Douglas fir. No permanent effects of this scorching are noted other than perhaps certain deficiencies of development on the most exposed sides of the trees. This form of injury is said to be analogous to the winter injury of white pine in Maine, as described by Morse (E. S. R., 21, p. 144). Parch blight is suggested as an expressive and distinguishing name for this injury.

The alternate hosts of the white pine blister rust, L. R. GROSE (*Amer. Forestry*, 22 (1916), No. 272, pp. 469-471, figs. 18).—Brief descriptions are given of the wild or cultivated currant and gooseberry, alternate hosts of the white pine blister rust. Species named as of particular importance in this connection

are *Ribes cynosbati*, *R. hirtellum* (or *R. oxyacanthoides*), *R. prostratum* (*R. glandulosum*), *R. americanum* (*R. floridum*), *R. triste*, *R. lacustre*, and *R. rotundifolium*. Maps are given to show the approximate range of each of these species in the Northeastern States and neighboring parts of Canada. Other native species are said to occur elsewhere, 70 out of a total of 120 species and subspecies being found in the United States, generally in the neighborhood of the five-leaved pines.

[The white pine blister rust situation], P. SPAULDING (*Amer. Forestry*, 22 (1916), Nos. 266, pp. 97, 98, fig. 1; 267, pp. 137, 138, fig. 1).—This information has already been noted (E. S. R., 35, p. 551).

White pines of Lenox menaced (*Amer. Forestry*, 22 (1916), No. 272, pp. 472, 473, fig. 1).—This is a brief account of the appearance, spread, and effects of blister rust among the noted white pines of Lenox, Mass., and of efforts now being made for control of the disease. In May and June of 1916 it was found to have attacked many white pines of all sizes and ages in this region, some trees having branches infected 60 or 70 ft. above the ground. Late in May the early summer stages of the blister rust appeared on currant and gooseberry leaves and the late summer form, which infects pine trees in the fall, was found late in June.

Conditions near Ipswich, Mass., have shown that there is no hope for the white pine trees that have been long exposed to the infecting spores from neighboring currant and gooseberry bushes.

*Endothia parasitica* and related species, C. L. SHEAR, N. E. STEVENS, and RUBY J. TILLER (*U. S. Dept. Agr. Bul. 380* (1917), pp. 82, pls. 23, figs. 5).—This bulletin gives an account of the taxonomy, morphology and development, and physiology of *E. parasitica*, the cause of the chestnut canker, and related species of the organism. To determine the specific identity of the organism, a study was made of all authentic specimens of all the species of *Endothia* obtainable.

According to the authors, the genus is divided into two sections based on the character of the ascospores. The first section contains two species, *E. gyrosa* and *E. singularis*, while the second section contains four species and one variety, *E. flueus*, *E. flueus mississippiensis*, *E. longirostris*, *E. tropicalis*, and *E. parasitica*. The host plants of the different species are mentioned, and *E. parasitica*, which is the only species thus far found to be actively parasitic, is reported to occur on *Acer*, *Carya*, *Castanea*, *Quercus*, and *Rhus*, but is known to be seriously parasitic only on *Castanea*. The oriental species of chestnut are said to be more or less resistant to the attack of this parasite.

A list of cited literature is appended.

Notes on some South African mistletoes and their hosts, R. MARLOTH and I. L. DREGE (*So. African Jour. Sci.*, 11 (1915), No. 10, pp. 402, 403, pl. 1; *abs. in Internat. Inst. Agr. [Rome]*, *Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 1, pp. 159, 160).—The genus *Viscum*, comprising about 60 species in various parts of the world, is said to be represented in South Africa by about 12 species. Among those which inhabit several hosts are *V. capense*, the most widely distributed species, *V. rotundifolium*, *V. obscurum*, and *V. crassulæ*.

*V. minimum* has been found only on *Euphorbia polygona* and only near Port Elizabeth. This plant is described as mainly an internal parasite, analogous in some respects to the fungi *Plasmopara viticola* on grape and *Peronospora infestans* on potato. It is said to require about two years to produce its first flowers, the fruit being much larger than the remaining portion of the plant exposed to view.

Some studies on Bordeaux mixture, B. F. LUTMAN (*Vermont Sta. Bul. 196* (1916), pp. 3-80, pls. 4, figs. 11).—The author gives the results of extensive studies on the fungicidal and physiological relations of Bordeaux mixture,

together with statements regarding the physical and chemical properties of that fungicide, particularly its settling, aging, preservation, etc. Notes are given on the efficiency of Bordeaux powder and Bordeaux paste as compared with freshly made Bordeaux mixture. The action of the fungicide on spore germination and its physical effect on various host plants, especially on potatoes, are described at length. In the case of the potato plant, control of flea beetle injury and tipburn by means of Bordeaux mixture are considered of much importance. The author recognizes the effect of different climates on the action of Bordeaux mixture, which, in the open fields of this station, seemed to have a favorable physiological effect.

Summarizing his investigations, the author states that dilute solutions may be used at a considerable saving. Thorough and violent stirring is said to break up the colloidal membranes, causing the mixture to settle slowly. Sphere crystals are formed in a short time from the copper salts in ordinary mixtures, and their covering power and adhesiveness are much less than those of colloidal membranes. A small quantity of cane sugar or glucose tends to preserve indefinitely the physical and chemical character of the fungicide. The copper in the thinner membranes is said to be immediately soluble and fungicidal, while that in the portions adjacent to the lime particles gradually becomes soluble. The lime in the mixture is also claimed to be fungicidal.

The action of Bordeaux mixture on the fungus spores is said to result in the killing of the spores, the retardation of their germination, or the putting forth of a short germ tube that is not likely to grow. Bordeaux mixture is claimed to kill largely by contact, the drip water not being highly fungicidal. Under field conditions this fungicide increases transpiration in freshly sprayed plants and increases the size of the cells, the chromatophores, and the nuclei. In the greenhouse or in a climate where neither tipburn, flea beetle injury, nor early or late blights occur, Bordeaux mixture does not seem to be either beneficial or harmful, but is quite unnecessary.

A bibliography is appended.

### ENTOMOLOGY.

Miscellaneous notes on injurious insects, P. J. PARROTT and H. E. HODGKISS (*New York State Sta. Bul. 423 (1916), pp. 359-387, pls. 8, figs. 4*).—These notes relate to the biology, economic importance, and treatment recommended for a number of fruit insects, which, though generally of minor importance, may become sufficiently numerous in occasional years to cause considerable damage, namely, the orchard ermine moths (*Yponomeuta malinellus* and *Y. padellus*), the peach leaf weevil (*Anametis granulata*), the lesser peach borer (*Synanthedon pictipes*), the lime-tree winter moth, the gooseberry fruit worm, and a green fruit worm on apple (*Graphiphora alia*).

The orchard ermine moths, an account of which by Parrott and Schoene has been previously noted (*E. S. R.*, 28, p. 557), are being introduced into the State in large numbers by importations of foreign-grown nursery stock, their infestation being largely confined to apple seedlings. Observations of the mining of leaves and other larval activities on apple are noted.

The peach leaf weevil is reported to have been present in destructive numbers during two different years in plantings of young peach trees in Niagara County. The opening buds and margins of unfolding leaves were eaten by the weevil, which deposits its eggs in clusters of from 3 to 40 in concealed situations, such as the folded edges of partially-expanded leaves or in recesses caused by a leaf being folded upon itself. Unusual numbers of the larvæ of the

lesser peach borer were observed in 1907 and 1908 in one orchard of peach and plum trees at Bellona. The notes given relate to their attack, nature of the injury, and habits of the species.

The lime-tree winter moth, which persists from year to year unnoticed in woodlands, appeared in conspicuous numbers in 1912 in fruit plantings. The gooseberry fruit worm occasionally attacks currant plantations, effecting serious losses in fruit yields through tunneling of the berries by the larvæ, which draw together fruit clusters and leaves by means of silken threads. Spraying with arsenate of lead or Paris green as the earliest webs were forming gave a large measure of protection from damages by the larvæ. Specimens of a type of green fruit worm, common in one orchard, which were reared to maturity proved to be *G. alia*.

Some new or rare fruit pests, F. H. HALL (*New York State Sta. Bul.* 423, popular ed. (1916), pp. 8, figs. 10).—A popular edition of the bulletin above noted.

Potato insects, R. L. WEBSTER (*Iowa Sta. Bul.* 155, popular ed. (1915), pp. 3-30, figs. 35).—A popular edition of the bulletin previously noted (E. S. R., 33, p. 352).

The insect fauna of New Jersey greenhouses, exclusive of the Coccidæ, H. B. WEISS, (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 2, pp. 144-150).—Forty-nine species, exclusive of the Coccidæ, are listed as occurring in greenhouses in New Jersey.

Cacao thrips and die-back in St. Vincent (*Agr. News [Barbados]*, 15 (1916), Nos. 369, pp. 206, 207; 370, pp. 222, 223).—A brief report of observations of the cacao thrips, and die-back of cacao made by the entomologist and mycologist in St. Vincent, who found that the conditions which are responsible for an outbreak of thrips in Grenada (E. S. R., 35, p. 357) have a similar effect in St. Vincent.

A synopsis of the genus *Oxythrips*, J. D. HOOD (*Insector Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 37-44).

A new *Plectrothrips* from Jamaica, J. D. HOOD (*Insector Inscitiæ Menstruus*, 4 (1916), No. 7-9, pp. 78-80, pl. 1).

Check list of the Hemiptera (excepting the Aphididæ, Aleurodidæ, and Coccidæ) of America, north of Mexico, E. P. VAN DUZEE (*New York: N. Y. Ent. Soc.*, 1916, pp. XI+111; rev. in *Psyche*, 23 (1916), No. 4, pp. 128, 129; *Ent. News.*, 27 (1916), No. 10, pp. 474, 475).—This check list, based upon a complete bibliographical and synonymical catalogue of the Hemiptera of America north of Mexico now in manuscript form, includes the systematic arrangement, full synonymy, date of each name, and general distribution of each species in addition to the numbered list of forms. The list enumerates 699 genera and 2,969 species, the Heteroptera being 465 and 1,477, respectively, and the Homoptera, 234 and 1,492. A list is given in the preface of new names proposed.

The reviews are by H. M. Parshley and J. R. de la Torre Bueno, respectively.

Remarks on *Lygus invitus*, with descriptions of a new species and variety of *Lygus*, H. H. KNIGHT (*Canad. Ent.*, 48 (1916), No. 10, pp. 345-349, figs. 2).—The author reports finding that *L. invitus* breeds only on the elm, preferring always the young thrifty plants with succulent shoots.

*L. communis*, here described as new to science and commonly known as the false tarnished plant bug, is a destructive enemy of the cultivated pear and is found commonly on *Cornus* spp. Life history studies of this pear pest under the name *L. invitus* by Parrott and Hodgkiss have been previously noted (E. S. R., 30, p. 358).

*L. communis novascotiensis* n. var., which breeds abundantly on apple in Nova Scotia, is also described.

The ash leaf bug, *Neoborus amoenus*, E. L. DICKERSON and H. B. WEISS (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 4, pp. 302-306, pl. 1).—This consists of descriptions of the several stages of and biological notes on *N. amoenus*, which injures the foliage of ash trees and has a much wider distribution in New Jersey than previously recorded.

Notes on cicadas from the United States with descriptions of several new species, W. T. DAVIS (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 1, pp. 42-65, pls. 4, figs. 9).—The author notes 15 species of which 6 are described as new to science.

The identity of *Eriosoma quercii*, A. C. BAKER (*Ent. News*, 27 (1916), No. 8, pp. 359-366, fig. 1).—*Anoecia quercii*, which occurs on Cornus, is shown to be the correct name for this aphidid. The species has been found to be distinct from the European *A. corni*.

*Monarthropalpus buxi* in New Jersey, H. B. WEISS (*Psyche*, 23 (1916), No. 5, pp. 154-156, pl. 1).—The European boxwood leaf miner is reported to occur in widely separated parts of New Jersey.

The susceptibility of the eggs of *Aphis pomi* and *A. avenae* to hydrocyanic acid gas formation, W. A. ROSS (*Canad. Ent.*, 48 (1916), No. 11, p. 367).—The author has found that when fumigated just before or shortly after the buds begin to swell the eggs of *A. pomi* and *A. avenae*, as well as the San José scale, on young trees are destroyed by hydrocyanic acid gas, 1 oz. to 100 cu. ft. (1:1:3), when exposed for 45 minutes.

Notes on the Psammocharidæ described by Provancher, with description of a new species, S. A. ROHWER (*Canad. Ent.*, 48 (1916), No. 11, pp. 369-372).—*Ceropaltes foxii* from Falls Church, Va., is described as new.

The shell-bark hickory mealy bug, A. H. HOLLINGER (*Canad. Ent.*, 48 (1916), No. 12, pp. 411-413).—Under the name *Pseudococcus jessica* the author describes a mealy bug which occurs on hickory at Columbia, Mo.

Contributions to the knowledge of the Dactylopiinæ of Hawaii, E. M. EHRHOEN (*Proc. Hawaii. Ent. Soc.*, 3 (1916), No. 3, pp. 231-247).—In this paper the author adds five genera, of which two (*Phyllococcus* and *Nesococcus*) are new to science, and eight new species, making a total of 25 species of Dactylopiinæ for the Hawaiian Islands.

An investigation of the best methods of destroying lice and other body vermin, J. P. KINLOCH (*Brit. Med. Jour.*, No. 2892 (1916), pp. 789-792).—In continuing investigations previously noted (*E. S. R.*, 34, p. 356) the author's experiments have substantiated the report by Bacot (*E. S. R.*, 36, p. 356) that lice do not survive immersion in boiling water.

"Several insecticidal powders have been tested, and of these N. C. I. powder [naphthalin, 96 per cent; creosote, 2 per cent, and iodoform, 2 per cent] is the most destructive to lice. Of the three constituents of N. C. I. powder, naphthalin and creosote have each a strong insecticidal action. The insecticidal action of iodoform is feeble. Naphthalin appears, so far as my comparative tests have gone, to be the most suitable basis for use in the preparation of a powder destructive to lice. Commercial naphthalin is more actively insecticidal than pure naphthalin, and it appears that the lethal power of naphthalin for lice is dependent in great part on the presence of hydrocarbons and coal-tar derivatives other than pure naphthalin. The immediate lethal effect of creosote when mixed with naphthalin is less than that of some other insecticidal liquids, but the longer period during which creosote continues to act more than compensates for the initial disadvantage. In addition to its feeble insecticidal activity, iodoform greatly increases the adhesiveness of N. C. I. powder for cloth. The inclusion of iodoform in the powder is accordingly justified, although similar adhesiveness of the powder is obtainable at less cost by substituting

the insecticidally inert but cheaper magnesium silicate for iodoform in the powder.

"The insecticidal power of naphthalin-cresote powders gradually diminishes when they are exposed in the open air. The moist nature of such powders precludes their being used successfully in perforated tins, and it has not been possible to dry the powders and at the same time retain the moist and volatile hydrocarbons and other coal-tar derivatives on which the insecticidal effect mainly depends."

Notes on Anoplura and Mallophaga, from mammals, with descriptions of four new species and a new variety of Anoplura, G. F. FERRIS (*Psyche*, 23 (1916), No. 4, pp. 97-120, figs. 12).—This paper is supplementary to that previously noted (E. S. R., 36, p. 253).

Notes on the feeding habits of adult Chrysopidæ, L. B. RIPLEY (*Ent. News*, 28 (1917), No. 1, pp. 35-37).—The author's observations of the feeding habits of adult Chrysopidæ have led him to conclude that (1) adults of both sexes feed upon smaller, soft-bodied insects, drink water, and discharge solid excrement; (2) unfed females die of starvation, leaving a large portion of their eggs unlaidd; and (3) females on the point of starvation eat their own eggs, extracting them from the abdomen as frequently as they are available.

A new species of Exoprosopa, F. R. COLE (*Ent. News*, 27 (1916), No. 10, p. 463, fig. 1).

A new species of Tortrix of economic importance from Newfoundland, A. GIBSON (*Canad. Ent.*, 48 (1916), No. 11, pp. 373-375, pl. 1).—Under the name *Tortrix oleraccana* the author describes a new lepidopteran, the larvæ of which in July, 1915, were very destructive to cabbage on farms near St. Johns, Newfoundland, and on one farm destroyed all of the first and much of the second plantings.

A caterpillar on the ears of wheat, W. SOMMERVILLE (*Jour. Bd. Agr. [London]*, 23 (1916), No. 3, pp. 263-238, fig. 1).—The caterpillar of the rustic shoulder-knot moth (*Hadena basilica*, also known as *Trachea* or *Apamea basilinea*) is said to have caused a considerable loss of wheat on experimental plats at Oxford.

Mosquitoes and man, A. H. JENNINGS (*Science*, n. ser., 44 (1916), No. 1128, pp. 201-203).—A discussion of a paper of the same title by C. S. Ludlow.<sup>1</sup>

New Aedes from the mountains of California, H. G. DYAR (*Insecutor Inscitiæ Menstruus*, 4 (1916), No. 7-9, pp. 80-90).

The earliest name of the yellow fever mosquito, F. KNAB (*Insecutor Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 59, 60).

Eggs and oviposition in certain species of *Mansonia*, H. G. DYAR and F. KNAB (*Insecutor Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 61-68, fig. 1).—This paper includes a description of *Mansonia humeralis* n. sp. from British Guiana.

Mosquitoes at San Diego, California, H. G. DYAR (*Insecutor Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 46-51).

The March fly (*Bibio abbreviatus*) in grain fields and as a pest of celery, E. H. STRICKLAND (*Agr. Gaz. Canada*, 3 (1916), No. 7, pp. 600-603, figs. 3).—In the autumn of 1913 and of 1914 a large percentage of the celery plants grown at the Dominion Experimental Station at Lethbridge, Alberta, were found to have been damaged extensively by larvæ of *B. abbreviatus*. This appears, however, to be an exceptional feeding habit of these larvæ, which, for the most part, feed on decaying material.

In the fall of 1914, when the celery was dug it was found that the larvæ had eaten away the soft pulp between the fibro-vascular bundles of the stalks of

<sup>1</sup> *Science*, n. ser., 43 (1916), No. 1118, pp. 784, 785.

celery to an average depth of  $\frac{1}{8}$  in. While the work of a single larva does not extend for more than about  $\frac{1}{4}$  in. between two of the vascular ridges, a large number swarm around infested plants so that the whole of the portion of the plant below the ground, some 9 in. in length, may be affected. Rarely larvæ burrow deeply into the pulp, thus forming small tunnels. In a typically attacked plant five of the largest stalks were seriously damaged and three to a lesser extent, the central stems not being damaged.

The attacked areas turn brown during the late summer and autumn, and are the seat of infection for various fungus diseases and small dipterous larvæ, such as *Drosophila*, which soon render the plants unfit for the market. Since the damage is to a large extent incidental to the method of bleaching celery by bringing it into contact with larvæ-infested earth, it is recommended that in localities where these larvæ occur in large numbers the celery be bleached between boards or prepared paper.

What is *Tabanus mexicanus*? F. KNAB (*Insector Inscitiæ Menstruus*, 4 (1916), No. 7-9, pp. 95-100, fig. 1).

Critical notes on Syrphidæ, F. KNAB (*Insector Inscitiæ Menstruus*, 4 (1916), No. 7-9, pp. 91-95).

Further notes on Syrphidæ, F. KNAB (*Insector Inscitiæ Menstruus*, 4 (1916), No. 10-12, pp. 133-135).

Notes concerning *Gastrophilus hæmorrhoidalis*, R. R. PARKER (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 4, pp. 253-255, fig. 1).—Observations of the peculiar shape of the egg of the nose fly or red-tailed bot (*G. hæmorrhoidalis*) have led the author to suggest that the pain which results when the egg is thrust into the nose or lips of a horse may account for the nervous and sometimes uncontrollable fear shown by the horse when the flies are "striking."

*Lithohypoderma*, a new fossil genus of oestrids, C. H. T. TOWNSEND (*Insector Inscitiæ Menstruus*, 4 (1916), No. 10-12, pp. 128-130).

Some notes concerning overwintering of the house fly, *Musca domestica*, at Dallas, Texas, W. E. DOVE (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 528-538).—The observations here reported, all of which were made at Dallas, Tex., have been summarized by the author as follows:

"Adult house flies having sufficient food, not subjected to fatal temperatures, killed by *Empusa muscæ*, nor destroyed by predators, show increased longevity in indirect proportion to decreases in temperature. The general tendency of adults to seek temperatures above 60° F. necessarily causes a shorter longevity than 91 days, which was obtained in a most favorable abnormal caged condition. The humidity being normal and adults being prevented from warmer temperatures, they become inactive at 45°, crawl slightly at 48°, and will voluntarily fly at 53°. Even previously fed adults, if subjected to freezing temperatures, die in less than three days. 'Northerners,' causing sudden drops in temperature, are responsible for a large mortality of flies in the vicinity of Dallas, Tex., yet warm periods occur during midwinter which permit depositing.

"There is a possibility that epidemics of *E. muscæ* may be caused by a lack of deposition media for flies which are sexually matured and have copulated. Breeding media ranging from 46 to 55° in 12 hours will permit emergence of adults from puparia, but emergence has never been observed at lower temperatures. Great numbers of pupæ near the surface of the soil receive either enough heat to permit emergence of adults, which usually succumb to cold before depositing or the temperatures are so low that they become inviable. Young larvæ have been kept for more than 67 days without pupating, but only

by occasional additions of small amounts of fresh manure. Larvæ more than one-half normal size have been kept alive for more than 90 days, and still other larvæ of various sizes have been observed to live for 115 days. Adults have been observed to emerge in an empty cage 6 ft. from a manure pile, the pupæ having been produced by migrating larvæ. The greatest larval migration was at least 8 ft. In a naturally accumulated and infested manure pile larvæ and pupæ were overwintered. Adults continued to emerge during mild weather in midwinter as long as manure was added. Emergence stopped when addition of manure ceased, but in spring at least 142 adults emerged."

Transmission of leprosy by the house fly (*Musca domestica*), E. MARCHOUX (*Ann. Inst. Pasteur*, 30 (1916), No. 2, pp. 61-68; *abs. in Rev. Appl. Ent., Ser. B*, 4 (1916), No. 6, pp. 85, 86).—The author concludes that the house fly may convey the leprosy bacillus on its recently soiled feet and proboscis, and that the bacillus can live in the digestive tract of this dipteran for at least four days.

Muscoid flies from the southern United States, C. H. T. TOWNSEND (*Insector Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 51-59).

Some new North American muscoid forms, C. H. T. TOWNSEND (*Insector Inscitiæ Menstruus*, 4 (1916), No. 7-9, pp. 73-78).—Six genera are erected and three species described as new, namely, *Ypophamyia malacosomæ* reared from pupæ of the tent caterpillar at Raleigh, N. C.; *Euzenilliopsis diatrææ* reared from larvæ of the sugar-cane borer in Cuba and from a pupa found in cane at Audubon Park, La.; and *Schizocerophaga leibyi* reared from pupæ of *Schizocerus privatus* at Raleigh, N. C.

On Australian Muscoidea, with description of new forms, C. H. T. TOWNSEND (*Insector Inscitiæ Menstruus*, 4 (1916), No. 4-6, pp. 44, 45).

Miscellaneous muscoid notes and descriptions, C. H. T. TOWNSEND (*Insector Inscitiæ Menstruus*, 4 (1916), No. 10-12, pp. 121-128).

Notes on the hen flea (*Echidnophaga gallinacea*), J. F. ILLINGWORTH (*Proc. Hawaii. Ent. Soc.*, 3 (1916), No. 3, pp. 252-254).—Substantially noted from another source (*E. S. R.*, 35, p. 58).

Flat-headed borers affecting forest trees in the United States, H. E. BURKE (*U. S. Dept. Agr. Bul.* 437 (1917), pp. 8, pls. 9).—Buprestid larvæ, known as flat-headed borers, are among the most important of the borers infesting forest trees in the United States, some mining the leaves, one burrowing into the cones, a number boring into the inner bark and outer wood of the trunk, branches, and roots, while the majority excavate oval-winding "wormholes" throughout the sound or decaying sapwood and heart wood.

The present paper reports largely upon the distinguishing characters of the larvæ of various species, including illustrations of many and a key to the genera of buprestid larvæ, together with a list of the genera which records their distribution, common habits, and host trees.

The pine bark beetle (*Ips pini*), W. A. CLEMENS (*New York Cornell Sta. Bul.* 383 (1916), pp. 287-298, pls. 2, figs. 4).—A report of studies of the life history and habits of *I. pini* extending over a period of three years.

The species is common and widely distributed, inhabiting the transitional and Canadian faunal zones ranging from the Pacific to the Atlantic and from about 37 to 55° north latitude. The damage which it causes is usually not of a serious character in itself, though it has been reported to cause the death of certain pines and spruces. In addition to direct injury it may be a source of loss by opening the way for the entrance of fungi and ambrosia beetles.

The winter is usually passed in the bark in the adult stage, migration taking place in the early spring. The eggs hatch in the galleries in five days, at a temperature of 69°, and the young larvæ then bore out into the cambium. The

pupal period lasts about five days. At Ithaca, N. Y., there are at least two generations and under very favorable conditions there may be three.

Its predatory enemies are usually common and its parasites are thought to be numerous. As regards control measures it is pointed out that the removal of the bark will cause the death of all larvæ and pupæ and if it is burned immediately after removal many adults will also be destroyed. Removal and burning of the bark in winter where the adults are known to be in hibernation will do much to lessen attacks in the season following. Where water is available the placing of newly felled logs in it will prevent injury by the beetles.

Mention is made of several common associates.

**Biological notes on *Ceutorhynchus marginatus*, S. W. FROST** (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 4, pp. 243-253, pls. 3).—The author has found the larvæ of this weevil to feed on the ovules and seeds of the dandelion at Ithaca, N. Y. The species is common throughout Europe but has been found in this country only in the Northeastern States.

**On some weevils attacking orchids, G. C. CHAMPION** (*Ent. Mo. Mag.*, 3. ser., 2 (1916), No. 21, pp. 200-202).—Under the name *Cholus cattleyæ* the author describes a new weevil which attacks orchids (*Cattleya gigas*) grown in a greenhouse in Bergen County, N. J., and at Milwaukee, Wis., that originated in tropical America. This appears to be the same species as that described by Barber in the paper previously noted (*E. S. R.*, 36, p. 360). A second species described as new to science, *Diorymellus lavimargo*, found attacking orchid roots in a greenhouse at Ithaca, N. Y., and in Bergen County, N. J., feeds on the leaves and flowers of orchids as well and also attacks the flowers of *Dendrobium*. This weevil also appears to have come from tropical America.

**Some unusual orchid insects, H. B. WEISS** (*Ent. News*, 28 (1917), No. 1, pp. 24-29, pls. 2).—Among the unusual species which have been found associated with orchids in New Jersey greenhouses are two weevils described by Champion and by Barber as noted above.

**A survey of beekeeping in North Carolina, E. G. CABE** (*U. S. Dept. Agr. Bul.* 489 (1916), pp. 16).—This is a report of a survey made in 19 counties in North Carolina from October 1 to December 22, 1915. It was made with a view to determining the present conditions, possibilities, and needs of the business of beekeeping, with special reference to the best means of supplying the needs.

The author has found that the State has a large number of bees, pollen and nectar-producing flora in abundance, and the honey when properly produced is of high grade and there is a good market for it. It is thought that extension work in beekeeping should be inaugurated as quickly and carried on as vigorously as circumstances will permit.

**The control of ants in dwellings.—A new remedy, A. GIBSON** (*Canad. Ent.*, 48 (1916), No. 11, pp. 365, 366).—The author has found sodium fluorid to control satisfactorily the common carpenter ant (*Camponotus pennsylvanicus*) and the common shed-builder ant (*Cremastogaster lineolata*) in buildings.

**Descriptions of various chalcidoid Hymenoptera, with observations, I and II, A. A. GIRAULT** (*Ent. News*, 27 (1916), Nos. 5, pp. 223-228; 9, pp. 401-405).—Among the 12 species described as new are *Pseudomphale ancylæ* reared from *Ancylus nubeculana*, Winchester, Va.; *P. steirastomæ* reared from larvæ of *Steirastoma depressum*, Erin, Trinidad; *Holycencyrtus physokermis* reared from *Physokermes picea*, Madison, Wis.; *Xenocrepis mexicana*, parasitic on a scymnid larva which preys upon *Lecanium oleæ* on orange at San Luis, and also from the larva of *Azya orbigera* at Monterey, Mex., in the first paper; and *Coccopygus aleurodici* reared from *Aleurodici* on *Theobroma bicolor*, Trinidad;

*Neocatolaccus syrphidis*, reared from a syrphid pupa, Trinidad, etc., in the second paper.

**Nine new species of Hymenoptera**, J. C. CRAWFORD (*Insecutor Inscitiae Menstruus*, 4 (1916), No. 7-9, pp. 101-107, fig. 1).—Among the species here described as new are *Tetrastichus pyrillæ* and *Ooencyrtus pyrillæ*, both reared from eggs of *Pyrilla aberrans*, and from Pusa and Nagpur, India, respectively.

**Some new American Hymenoptera**, J. C. CRAWFORD (*Insecutor Inscitiae Menstruus*, 4 (1916), No. 10-12, pp. 135-144).—One genus, seven species, and one variety are here described as new, among which are *Fidiobia rugosifrons* described from eggs in wheat stubble at Montoursville, Pa.; *Microdontomerus fumipennis* reared from *Malacosoma fragilis* at Maxwell, N. Mex.; *Ptinobius texanus* reared from *Otidoccephalus carinicollis* at Dallas, Tex., *Trichobaris texana* at Victoria, Tex., and *Aræocerus fasciculatus* at Hallettsville, Tex.; and *Perilampus chrysopæ lavicephalus* reared from *Chrysopa californica* at Sacramento, Cal.

**Descriptions of miscellaneous chalcid flies**, A. A. GIRAULT (*Insecutor Inscitiae Menstruus*, 4 (1916), No. 10-12, pp. 109-121).—Twenty new species are here described, of which mention should be made of *Tetrastichus malacosomæ* reared from the eggs of the tent caterpillar and the forest tent caterpillar at Berkeley, Cal., and from the eggs of *Malacosoma fragilis* at Maxwell, N. Mex.; *Eurytoma ctenodactylomyii* and *Neocatolaccus livii*, both reared from the galls of *Ctenodactylomyia watsoni* on sea-grape (*Coccoloba urifera*) in Porto Rico; *Elasmus mordax* reared from *Lithocolletis guttifinitella* in the District of Columbia; *Pachyneuron mucronatum* reared from an aphid at Guanajuato, Mexico; *Elasmus aspidiscæ* reared from a cocoon of *Aspidisca splendoriferella* on *Cratægus* in the District of Columbia; and *Isodromus abnormicornis* reared from *Icerya brasiliensis* at São Paulo, Brazil.

**A remarkable new genus of Encyrtidæ from the West Indies**, bearing two ring joints, A. A. GIRAULT (*Jour. N. Y. Ent. Soc.*, 24 (1916), No. 3, pp. 232, 233).—The author describes *Ancromyzobia aphelinoides* n. g. and n. sp. from St. Vincent, West Indies.

**A new genus of Tetrastichini (chalcidoid Hymenoptera)**, A. A. GIRAULT (*Ent. News*, 27 (1916), No. 8, p. 348).—The genus *Galeopsomyia* is erected for *Eudcrus columbianus*.

**The North American species of Dibrachys (in the North American sense—Cælopesthoidea) with a note on Uriella**, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 12, pp. 408, 409).

**A new species of Lepidopria from North America**, C. T. BRUES (*Psyche*, 23 (1916), No. 4, pp. 126, 127, fig. 1).—*Lepidopria aberrans* reared from a tachinid pupa, probably *Cryptomeigenia theutis*, found in an adult June beetle (*Phyllophaga* [*Lachnosterna*] *inversa*) at Hagerstown, Md., is described as new to science.

**Notes on the egg parasites of the apple tree tent caterpillar (*Malacosoma americanum*)**, L. T. WILLIAMS (*Psyche*, 23 (1916), No. 5, pp. 148-153).—The author presents notes on six species of parasites (*Ablerus clisiocampæ*, *Telenomus clisiocampæ*, *Tetrastichus* spp., *Ooencyrtus clisiocampæ*, and *Aphycoideus io*) reared from the eggs of the tent caterpillar, their behavior, and relative abundance.

**New chalcid flies from Maryland**, A. A. GIRAULT (*Ent. News*, 28 (1917), No. 1, pp. 20-23).—Two genera and six species are described as new to science.

**The occurrence of *Neoderostenus* Girault in North America**, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 12, p. 409).

A new genus of omphaline eulaphid chalcis flies from Maryland, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 12, p. 410).—*Euderomphale fuscipennis* n. g. and n. sp. from a meadow at Glendale, Md., is here described.

Descriptions of and observations on some chalcidoid Hymenoptera, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 10, pp. 337-344).—This paper includes descriptions of nine new species representing the genera Eurytoma, Rileya, Asympsiella, Pleurotropis, Ormyrus, and Habrolepoidea, among which is *A. india* reared from the tar leaf-folder (*Gracillaria soyella*) at Pusa, India; and *H. depressa* reared from the eggs of *Cyrtene robiniae* at Morristown, Ill.

The occurrence of the genus *Achrysocharelloidea* in North America, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 10, p. 336).

The red spider on cotton, E. A. MCGREGOR and F. L. McDONOUGH (*U. S. Dept. Agr. Bul.* 416 (1917), pp. 72, pls. 8, figs. 21).—This is a detailed report of studies of *Tetranychus bimaculatus*, its life history and habits, seasonal history, dispersion, insect enemies, and remedial measures, together with descriptions of its several stages. While occurring throughout the United States, it is known as a serious pest in only three regions, namely, in that portion of the cotton belt including North Carolina, South Carolina, Georgia, Florida, Alabama, and Mississippi, where it is primarily a pest of cotton; in north-central and western Colorado as a pest of fruit trees; and in central California, where the species is a rather serious pest of hop fields (*E. S. R.*, 29, p. 261). It is estimated that during a season of severe red spider occurrence the loss to the cotton planters of the Southeast amounts to approximately \$2,000,000. Investigation has shown that it can maintain itself successfully on 183 species of wild and cultivated plants, weeds, vines, bushes, and trees.

"The control of the red spider is possible either by preventive or by repressive measures. Great expenditures of time, labor, and material, however, are necessary when the latter operation is undertaken. . . . Clean culture, or the extermination of weeds and plants which breed the pest, is by far the most vital means of prevention that can be applied in the case of field and truck crops. In cases where cotton is grown within 100 yds. of dooryards containing violets and other ornamental plants a careful watch of these plants should be maintained in order that they may be sprayed or destroyed. By the persistent maintenance of a finely pulverized surface mulch in fields the progress of migrating mites is somewhat retarded and the development of infestation correspondingly discouraged. . . . Trap crops, rotation, favorable planting time, irrigation, etc., are either of only slight or of negative value.

"Dispersion may be prevented by eliminating the plants in a field which harbor the initial infestation. This may be accomplished by pulling the first few plants which show infestation, or, in case the pest has secured a good foothold, the elimination will be accomplished only by means of plowing up all the affected portion of the field. In either case the stalks should be quickly piled and burned with the help of a little straw or light trash.

"Spraying for red spiders is effective if it is done with extreme care. There are a few sprays which will give complete mortality when properly applied, but a second spraying is necessary to kill the individuals that were eggs at the time of the first spraying. A contact insecticide is absolutely necessary, and it is vital that every leaf on an infested plant should be reached by the spray."

A bibliography of four pages is included. A report of studies of this mite in Oregon by Ewing has been previously noted (*E. S. R.*, 32, p. 156).

The sexual evolution of *Sarcocystis muris*, H. CRAWLEY (*Proc. Acad. Nat. Sci. Phila.*, 68 (1916), pt. 1, pp. 2-43, pls. 5).

## FOODS—HUMAN NUTRITION.

Studies of the values of different grades of milk in infant feeding, R. M. WASHBURN and C. H. JONES (*Vermont Sta. Bul. 195 (1916), pp. 144, pls. 9, figs. 10*).—The experiments reported in this bulletin were carried out with baby pigs, with the view of adapting the findings to infant feeding.

Studies of the effect of feeding skim, medium, and rich milks showed that "the character of the tissue produced is determined by and closely parallels the chemical composition of the food consumed. A ration supplying a large amount of protein in proportion to the total energy available (e. g., skim milk) produced sturdy, agile, but rough and undersized pigs. Milk carrying a medium fat content (2.5 per cent) and, hence, less protein in proportion to the total units of energy available than does skim milk, produced healthy, 'growthy,' active, yet smooth and fair-sized pigs. Milk containing a large quantity of fat (5 per cent) in proportion to protein, produced a rapid increase in weight and physiologically economical gains; but the pigs were in a dangerously overfat condition and betrayed peevishness and low vitality. The body of the young pig and, if the results of these trials are applicable to human infant feeding, that of the human young, should not contain much more than approximately 1.6 parts of fat for every one part of protein. If a ration carrying a nutritive ratio of about 1:3 is used, a 1:1.6 result, or an approximation to such a result may be expected."

From their study of the relative values of Holstein and Jersey milks, the authors are of the opinion that the size of the fat globules has no practical bearing on the relative values of milks in infant feeding, and that any superiority for infant feeding attributed to Holstein milk is more likely to lie in its relatively low fat content than in the relatively small size of the fat globules.

The evidence obtained in experiments with homogenized milk indicated that homogenization of the fat does not seem to be helpful in feeding the young. "The pigs fed the milks thus treated ate their food less greedily and, whenever the fat content of their ration was increased, went 'off feed' more quickly than did those receiving milk containing normal fat. However, the curds formed from milk the casein of which had been homogenized were made so much more flocculent and friable as a result of this process that [it appears] that perhaps benefit may be expected from such treatment. The quantity of fat fed is of much more importance in the constitution of the body tissue than is the size of the fat globules." When medium amounts of fat (2 to 3 per cent) were fed there appeared to be a slightly increased fat utilization favoring homogenization.

Tests of evaporated (unsweetened) and condensed (sweetened) milks showed that both were readily digested and assimilated and their nutrients appropriated for tissue growth. "Evaporated milk compared very favorably indeed with normal milk, standardized to a medium fat percentage, in nutriment and in tissue production." While sweetened condensed milk showed an abundant energy value it proved an undesirable food for the young, since its nutrients were so proportioned as to produce a weak and dangerously fat body.

The question of the effect of food upon the structure of the bones was studied, particularly on account of its relation to rickets and other forms of malnutrition. From these tests the following conclusions were drawn: "The femur of the average pig fed sweetened condensed milk was but two-thirds as strong as that formed when normal milk was fed. Only a slight difference appeared between the normal and the evaporated milk groups in regard to the breaking strength of their femurs, but this difference favored the normal

product. In spite of the high ash percentage utilization by the pigs fed sweetened condensed milk, their body gain contained less ash than did the gains of either the normal or the evaporated-milk-fed-animals. Tricalcic phosphate does not seem to be a particularly available form in which to furnish lime and phosphoric acid."

Although the authors state that definite conclusions can not be drawn on this point, somewhat limited trials indicated that overdilution of the milk rations tended to lessen their food value.

In conclusion the authors discuss at length the principles of infant feeding in light of these experiments and clinical evidence. Special attention is given to the American, or percentage system, and the German, or calorific system, of infant feeding and to suggestions for a combination of these two methods. The compositions of human, cows', and sows' milks are compared. There is also an extended discussion of the digestion of milk which touches mainly on the following points: Casein digestion, the effect of colloids and cereals on curd structure, the rate of coagulation in the stomach, digestion of milk serum, and fat digestion.

A bibliography of cited literature is included, together with an appendix, which contains the clinical records of the animals used as subjects of the experiments.

Value of different grades of milk in infant feeding, R. M. WASHBURN and C. H. JONES (*Vermont Sta. Bul.* 201 (1916), pp. 32, pls. 4, figs. 6).—This is a popular edition of Bulletin 195, noted above.

Studies of infant feeding.—The chemical changes produced by the addition of limewater to milk, A. W. BOSWORTH and H. I. BOWDITCH (*Jour. Biol. Chem.*, 28 (1917), No. 2, pp. 431-435).—The results of this investigation showed that although the addition of limewater to milk increases the total amount of CaO, it results in a marked change in the arrangement of the salts, bringing about the precipitation of calcium, phosphorus, and citric acid, a mixture of dicalcium (CaHPO<sub>4</sub>) and tricalcium (Ca<sub>3</sub>P<sub>2</sub>O<sub>8</sub>) phosphates being the insoluble phosphates formed. By the addition of limewater the reaction of the serum of milk is brought toward the neutral point, the soluble alkalinity of the limewater being used up in the precipitation of the insoluble calcium phosphates.

"When milk to be used for infant feeding is treated with limewater and finally diluted to such an extent that it has twice the volume of the original milk, or more, the soluble calcium and phosphorus may be reduced to amounts less than those which are present in human milk."

The influence of the coagulation by rennin upon the gastric digestion of milk protein, J. T. LEARY and S. H. SHEIB (*Jour. Biol. Chem.*, 28 (1917), No. 2, pp. 393-398).—The object of this investigation was to throw some light upon the differences in results obtained by other workers regarding the influence of the coagulation by rennin upon the subsequent gastric digestion of milk protein.

The data obtained confirmed the results of Abderhalden and Kramm,<sup>1</sup> who found that clotted milk was more easily digested than milk in which coagulation had been prevented by the use of an oxalate, but in the latter case peptic digestion was believed to be inhibited by the presence of the oxalate solution. The internal digestion of the paracasein curd by adsorbed pepsin is deemed of rather minor importance. Through a slightly different method from that employed by Hawk (*E. S. R.*, 15, p. 494), his conclusions were verified that pepsin acts much more readily upon the protein constituents of milk where no thick, elastic curd of paracasein is formed. The formation of the curd of paracasein was found to depend upon the strength of the hydrochloric acid

<sup>1</sup> *Ztschr. Physiol. Chem.*, 77 (1912), No. 6, pp. 462-470.

in the juice and the quantity of rennin present. The peptic digestion of boiled milk was slightly more rapid than that of raw milk.

**Cereal foods in the course of history**, A. MAURIZIO (*Die Getreide-Nahrung im Wandel der Zeiten*. Zurich: Orell Füssli, 1916, pp. V+237, figs. 53).—This book summarizes information regarding the production, preparation, and use of cereals in various parts of the world from prehistoric times to the present day, among the people of all grades of civilization, including primitive races. Notes are also given on the use of some food plants other than cereals and on many types of so-called famine and war breads. Many types of cereal foods found in the Balkan and Scandinavian peninsulas are described. The publication contains many illustrations of grinding and milling devices, ovens, cooking utensils, etc.

**Milling and baking tests of Victorian wheat**, P. R. SCOTT and F. G. B. WINSLOW (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 11, pp. 641-652, figs. 2).—The results are reported of tests made of several samples of wheat grown during the season 1915-16 at the different experimental farms, continuing previous work (E. S. R., 33, p. 659).

**Is lysin the limiting amino acid in the proteins of wheat, maize, or oats?** E. C. McCULLOM, N. SIMMONDS, and W. PITZ (*Jour. Biol. Chem.*, 28 (1917), No. 2, pp. 483-499, pl. 1, figs. 12).—The experiments here reported showed the following results:

Zein does not supplement the protein in the wheat or maize kernel so as to improve the rate of growth of young laboratory animals (rats). Zein does, however, supplement the protein of the oat kernel in an efficient manner, although it lacks tryptophan and lysin, and is one of the poorest proteins in cystin. In the protein of the oat kernel, therefore, these amino acids are eliminated as being possibly the essential protein cleavage products present in minimal amount, and determining the plane of intake essential for growth.

"Gelatin chemically supplements the protein mixture of both the wheat kernel and oat kernel, respectively. Since gelatin contains no tyrosin or tryptophan, and but a trace of cystin, but contains 6 per cent of lysin, it is evident that neither tyrosin, tryptophan, nor cystin is the limiting amino acid in these grains. It tends to support the view, but does not prove, that lysin is the amino acid whose addition alone to the wheat protein mixture raises the biological value of the latter."

The addition of wheat gluten to the wheat or maize kernel proteins supplements them so as to improve growth. The proteins of the wheat gluten, as a mixture, are probably qualitatively adequate as regards all of the indispensable amino acids, although this point is not definitely established.

The authors state that the combinations of wheat gluten with wheat-kernel proteins or maize-kernel proteins led to growth probably because of a higher intake of protein rather than a supplementary relationship between the proteins from the two sources in the sense of one making up for the amino-acid deficiencies of the other. The results of feeding maize proteins with wheat gluten are of particular interest, however, because of their pronounced effect in promoting growth despite the relatively low lysin content of both the wheat and maize proteins.

"Gelatin with its high lysin content does not improve the proteins of the maize kernel."

**Homemade bread substitutes for diabetic patients**, R. T. WILLIAMSON (*Brit. Med. Jour.*, No. 2921 (1916), pp. 870, 871).—Recipes are given.

**Potatoes, sweet potatoes, and other starchy roots as food**, C. F. LANGWORTHY (*U. S. Dept. Agr. Bul.* 468 (1917), pp. 29, figs. 7).—This bulletin summarizes general and experimental data regarding the composition, nutritive value, and

cookery of the potato, sweet potato, Jerusalem artichoke, and some tropical starch-bearing roots—the cassava, yam, dasheen, yautia, and taro. There is also a discussion of some potato products (starch and dried and canned potatoes), the selection of potatoes for the table, and the effect of storage on quality. The bulletin is a revision in part of Farmers' Bulletin 295 (E. S. R., 19, p. 164).

Canned tomatoes, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 357* (1916), pp. 31).—This bulletin reports the results of the inspection of 232 samples of canned tomatoes purchased in various parts of the Dominion of Canada.

Determinations of preservatives in caviar, KÖPKE (*Arb. K. Gsndhtsamt., 50* (1915), No. 1, pp. 31-37).—Data are given regarding the composition of different samples of commercial caviar and the amounts of preservatives found, together with some discussion of the methods used.

The nutritive value of wood, G. HABERLANDT (*Sitzber. K. Preuss. Akad. Wiss., 1915, XIV, pp. 243-257*).—The starch, fat, and protein content of different kinds of wood, different sections of the same kind, and its seasonal variations are discussed.

Original measurements of the proportion of starch-holding tissues of typical trees are reported, from which the author concludes that such tissues make up from  $\frac{1}{4}$  to more than  $\frac{1}{4}$  of the total volume of the wood. The reserve stores of starch and fat within the wood are considered highest in autumn and winter. The literature relating to the utilization of wood as food for man and domestic animals is reviewed and the conclusion drawn that the finely-ground substance of the growing wood from certain trees could be combined with flour in bread making, providing some method of treating the cellulose could be found which should make the nutrients it surrounds accessible to the digestive juices.

The iodine content of food materials, R. M. BOHN (*Jour. Biol. Chem., 28* (1917), No. 2, pp. 375-381).—The author reports results of determinations of iodine made upon a variety of foods and feeding stuffs, two natural waters, and several rock salts. Three methods for the determination of iodine in organic matter were compared, the one proposed by Kendall<sup>1</sup> being regarded by the author as the most accurate.

The majority of samples contained no iodine, although some showed the presence of a trace. The author concludes that the presence of iodine in feeding materials of vegetable origin "is accidental and serves no necessary nutritive function in the plant. Further, the iodine requirements of animals must of necessity be met by the traces that occur in plant materials, waters, etc."

The results obtained are in agreement with those of Forbes, Beegle, et al. (E. S. R., 35, p. 761).

[Eighteenth and nineteenth annual conventions of the Association of American Dairy, Food, and Drug Officials] (*Proc. Assoc. Amer. Dairy, Food, and Drug Officials, 18* (1914), pp. 472, figs. 16; 19 (1915), pp. 228).—These publications report, respectively, the proceedings of the meetings at Portland, Me., July 13-18, 1914, and Berkeley, Cal., August 2-5, 1915.

Among the papers read at the 1914 meeting were the following: Regulation of Food Supplied Hotels, with Particular Reference to Sanitary Conditions Involved in Its Preparation, by G. G. Frary; When Is an Orange Mature and Wholesome, by R. E. Rose; Egg Albumin in Baking Powders, by E. F. Ladd; Cause of Variation in Weight or Measure of Food Products, by L. M. Tolman and W. E. Hillyer; Ice Cream Standards—Necessity for Standards, by W. B. Barney; Ice Cream Standards, by J. G. Winkjer; and State Drug Inspection, by A. R. Todd.

<sup>1</sup> Jour. Biol. Chem., 19 (1914), No. 2, pp. 251-256, fig. 1.

Those presented in 1915 included the following: Exclusion from Official Establishments of Employees Affected with Communicable Disease, by H. H. Hicks; Effect of Storage on Coffee, by R. E. Doolittle and B. B. Wright; Effect of Storage on Moisture Content of Cloves, by A. W. Ogden; Physical Examination of Employees Handling Food Products—Necessity, Progress Made, Outlook, by H. E. Barnard; and Sanitary Problems of the Soft Drink Establishment, by G. B. Taylor.

The reports of the various committees are given for each year.

The sanitation of public markets, D. B. ARMSTRONG (*Jour. Amer. Med. Assoc.*, 68 (1917), No. 2, pp. 103-106).—In this paper the major points discussed are the control of the quality of the products by laboratory examination, which includes chemical, bacteriological, and calorific analyses; the condition of the market building; sanitary aspects of the market equipment and the methods of handling food; and administrative control. Special emphasis is laid upon the importance of the health and cleanliness of the employees, as essentials to which are given a living wage, the selection of healthy persons as employees, periodic medical examinations, and the provision of adequate sanitary toilet and hand-washing facilities.

Three delicious meals every day for the farmer, G. W. CARVER (*Alabama Tuskegee Sta. Bul.* 32 (1916), pp. 13).—This bulletin suggests an increase in the amount and kind of foods raised on the farm, and includes menus for one week, together with some recipes. It is intended especially for the use of negro farmers in the South.

The rural school lunch, NELLIE W. FARNSWORTH (*St. Paul, Minn.: Webb Publishing Co.*, 1916, pp. 42, figs. 12).—Information is given regarding equipment and service. Recipes are included.

Typical electric range designs, E. A. WILCOX (*Jour. Electricity*, 38 (1917), No. 1, pp. 13, 14, figs. 4).—Descriptions are given of different types of electric heating units and ranges.

The effects on higher animals of the sterilization of the inhabited medium, the air, and the food, I. KIANIZIN (*Jour. Physiol.*, 50 (1916), No. 7, pp. 391-396).—This is a summary and digest of experiments by the author, as well as of those of other investigators, along this line.

It is stated that in the author's experiments higher animals soon died when the micro-organisms were absent from the air and food, the length of life varying in different animals. The experiments of numerous other investigators showed that the absence or partial absence of micro-organisms has a deleterious effect on nutrition. The author states that the micro-organisms of air are essential to life, and that in the absence of micro-organisms an imperfect assimilation of nitrogen compounds occurs.

Studies of the gastric residuum.—I, A study of 80 samples of gastric residuums obtained from apparently normal women, C. C. FOWLER and ZELMA ZENTMIRE (*Jour. Amer. Med. Assoc.*, 68 (1917), No. 3, pp. 167-170, figs. 4).—The observations here reported did not give evidence of any striking differences between the gastric residuums of normal women and normal men. The average volume found was approximately 49 cc.

Pancreatic diabetes in the dog.—IV, The influence of pylorus exclusion and of gastrectomy upon the effects of pancreatectomy, J. R. MURLIN and J. E. SWEET (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 261-288).—The results of these experiments with laboratory animals (dogs), taken in conjunction with the results of the work of another investigator, which shows the extreme sensitiveness of the mechanism for the oxidation of glucose to the concentration of hydrogen ions, and earlier work by the senior author, which demonstrates the beneficial effect on the oxidation of glucose of administered alkali to totally

and partially depancreatized dogs suggest that "the internal function of the pancreas may be closely akin to its external function in that, on the one hand (external), it provides for the complete neutralization of the acid contents of the stomach, thereby protecting the liver in its glycogenic function, and on the other (internal), it somehow preserves the proper concentration of hydrogen ions in the tissues for combustion of glucose."

**Scurvy in Zhob, Baluchistan, A. L. SHEPPARD** (*Indian Jour. Med. Research*, 4 (1916), No. 2, pp. 340-358).—In the light of his experience as medical officer, the author discusses the occurrence of scurvy in this region, together with the etiology of the disease, its symptoms, etc.

### ANIMAL PRODUCTION.

**Digestibility of the cell wall of wood, G. HABERLANDT and N. ZUNTZ** (*Sitzber. K. Preuss. Akad. Wiss.*, 1915, XLI, pp. 686-708, fig. 1).—This reports the results of an anatomical and microscopical study of birch wood, the preparation and microscopical nature of birch-wood dust (ground wood), the chemical constitution of birch wood and dust, a metabolism experiment with a sheep to determine the digestibility and evaluation of birch-wood dust as a feeding stuff, and a microscopical examination of the excrement of the experimental animal. The wood examined was found to have the following percentage composition: Water 4.56; nitrogen, 0.108 (protein, 0.675); ether extract, 0.45; nitrogen-free extract, 61.56; crude fiber, 32.3; and ash, 0.46.

The experimental animal received a daily ration consisting of 450 gm. of wood dust, 30 gm. of wheat gluten, 100 gm. of molasses, and 75 gm. of starch, together with 5 gm. calcium carbonate and 100 cc. of salt solution containing 5 gm. sodium acid phosphate, 1 gm. magnesium sulphate, and 3 gm. sodium chlorid. From the results obtained it is concluded in general that partially or completely wooded cell walls such as occur in birch wood are to a very large extent digestible by ruminants. The complete comminution of the wood, which was principally to liberate the cell contents, also destroys the cell walls, thus making them more digestible.

The question as to the value of this material for other ruminants is noted and a further study to determine the practical value of its feeding is indicated.

**Commercial feeding stuffs, 1915-16, C. D. WOODS** (*Maine Sta. Off. Insp.*, 79 (1916), pp. 53-136).—Tabulated data are given showing registrations of feeding stuffs and notes on the results of the examination of 675 samples. A brief statement is presented by A. M. G. Soule upon the results of feeding-stuffs inspection in the State in 1915-16.

**Commercial feeding stuffs, J. L. HILLS, C. H. JONES, and G. F. ANDERSON** (*Vermont Sta. Bul.* 197 (1916), pp. 45).—These pages contain notes on the results of the 1916 inspection. The large percentage of samples deficient in the claims of the guaranty is noted.

**Cottonseed meal compared with velvet beans for fattening steers, G. S. TEMPLETON and E. GIBBENS** (*Alabama Col. Sta. Bul.* 192 (1916), pp. 135-141, pls. 2).—A comparison was made of the relative feeding value of cotton-seed meal and velvet beans in pods as supplements for corn silage for fattening steers. Forty native 1 to 2 year old grade Hereford, Shorthorn, and Angus steers averaging about 584 lbs. were used in the test. The experiment, which began December 18, 1915, and lasted 97 days, was conducted under average farm conditions at Allenville, the steers being fed in the open. Twenty of the steers were fed cottonseed meal at the rate of from 2.76 lbs. per steer daily at the beginning to 6.46 lbs. at the end of the experiment, and the other 20 steers velvet beans at the rate of from 5.7 lbs. at the beginning to 12 lbs. when on

full feed. The velvet beans and pods were ground coarse for two weeks but after this they were fed unground, both the unground and ground velvet beans being mixed with the silage.

The steers on cottonseed meal consumed 2.58 lbs. of meal and 24.09 lbs. of silage per pound of gain and gained 1.6 lbs per head daily at a cost of 7.52 cts. per pound of gain. Those on velvet beans consumed 6.36 lbs. of beans and 16.55 lbs. of silage per pound of gain and gained 1.5 lbs. per head daily, the cost per pound of gain being 7.77 cts. In this test cottonseed meal was valued at \$35, velvet beans \$18, and corn silage \$2.50 per ton. It is estimated that 1 lb. of cotton-seed meal was equal to 2.5 lbs. velvet beans in pods for these steers.

**Cattle feeding.—XII, Winter steer feeding, 1915–16, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul. 191 (1916), pp. 35; pop. ed., pp. 8*).**—In the experiments reported in this bulletin, which are in continuation of those already noted (*E. S. R., 35, p. 475*), the cattle and the feed were both of poor quality, and as a result the gains were below normal.

Seven lots of 10 steers each were fed for 150 days, all the lots receiving shelled corn, and all except lot 6, 2.5 lbs. of cottonseed meal per 1,000 lbs. live weight in addition to the supplements given in the table below. Each lot of cattle contained 10 hogs. All of the hogs received corn in addition to droppings from the cattle, and 5 hogs in each of lots 2, 3, and 4 received a small quantity of shorts and tankage.

In a comparison of corn silage and leguminous hay *v.* leguminous hay for fattening steers, involving lots 2, 3, 4, and 7, it was found that corn silage in the ration reduced the amount of corn required and practically replaced the hay. Only about 2.5 lbs. of hay per head daily was consumed by the lots on silage. With clover hay as roughage replaced by 14.2 lbs. of corn silage there was a saving of 1.5 lbs. of corn and 5.6 lbs. of hay on every pound of gain. With alfalfa hay as roughage there was a saving of 1.91 lbs. of corn and 4.97 lbs. of hay by the use of 13.11 lbs. of silage.

In a comparison of clover hay *v.* alfalfa hay as roughage for fattening steers, involving lots 2, 3, 4, and 7, the results indicate that for all practical purposes these two hays are of equal worth when furnishing the only roughage. However, when both hay and silage were fed, the steers receiving alfalfa hay excelled those receiving clover hay in every factor except in pork production.

A limited feed of corn was compared with a full feed of corn for fattening cattle, involving lots 1 and 4. Lot 1 received the following amounts of shelled corn per steer daily: First month none, second month 5 lbs., third month 7 lbs., fourth month 8 lbs., and fifth month 9 lbs. Lot 4 received all the shelled corn they would eat. The average difference in corn consumption for the two lots during the entire period was 4.01 lbs. per steer daily. Lot 1 consumed 3.09 lbs. of clover hay and 33.01 lbs. of silage, as compared with 2.04 lbs. of clover hay and 28.64 lbs. of silage for lot 4. Limiting the amount of corn saved 1.84 lbs. of corn on each pound of gain made by the cattle, this being replaced by 0.06 lb. of cottonseed meal, 0.6 lb. of clover hay, and 2.96 lbs. of silage.

In a comparison of cane feeding molasses *v.* proprietary molasses feed as supplements to rations for fattening cattle, involving lots 4, 5, and 6, it was found that the substitution of a small quantity of molasses for an equal quantity of corn increased the appetites of the steers, especially during the latter part of the feeding period. The increase of feed consumption was mostly of corn silage, the average amount of silage eaten per steer daily being 4 lbs. more when molasses was used. The substitution of proprietary molasses feed for cottonseed meal caused only a slightly larger feed consumption on the part of the cattle.

Other data in reference to these comparisons and upon the experiments in general are given in the following table:

*Steer-feeding trials.*

Lot.	Variable portion of ration.	Average daily gain per head.	Cost per pound of gain.	Selling price per pound.	Profit per steer, not including pork.	Pork produced per lot.	Profit per steer, including pork. <sup>1</sup>
		<i>Lbs.</i>	<i>Cts.</i>	<i>Cts.</i>		<i>Lbs.</i>	
1	Clover hay and corn silage.....	1.92	10.55	8.60	\$9.26	1,143	\$14.63
2	Clover hay.....	2.09	12.33	8.65	3.97	1,107	9.55
3	Alfalfa hay.....	2.06	12.23	8.65	4.09	1,203	10.59
4	Clover hay and corn silage.....	2.02	11.39	8.70	7.60	1,156	13.61
5	Cane molasses, clover hay, and corn silage.....	2.25	11.35	8.75	7.48	855	11.52
6	Molasses feed, clover hay, and corn silage.....	1.90	12.73	8.60	3.16	1,125	9.24
7	Alfalfa hay and corn silage.....	2.35	9.93	8.75	12.10	1,075	17.61

<sup>1</sup> Cost of additional feed consumed by hogs deducted.

Feed costs and profits in these experiments were based upon the following figures: Initial value of steers 6.9 cts. per pound; pork 9.75 cts. per pound; corn 55.9, 62.5, 62.4, 58.2, and 63.7 cts. per bushel from the first to the fifth months, respectively; and cottonseed meal \$38, molasses feed \$31, cane molasses \$30, clover hay and alfalfa hay \$12, and corn silage \$4.50 per ton.

**Skim milk and milk substitutes for calf feeding,** O. F. HUNZIKER and R. E. CALDWELL (*Indiana Sta. Bul. 193 (1916), pp. 3-104, figs. 31*).—In these experiments three lots of 10 calves each, for the most part pure-bred Jerseys, Holsteins, and Ayrshires, were fed for 182 days. Individual photographs taken under standard conditions to show the physical condition and variations in size, representing six 30-day periods in the first six months in each calf's life, are reproduced together with a tabulated average daily summary of the feeds consumed, composition and cost of ration, and variations in live weight for each of the 26 weeks of the experiment.

All the calves remained with their dams until four or five days of age, at which time they were placed on bucket feeding. The calves in lot 1 were fed whole milk until they were three weeks old, the whole milk being gradually replaced by skim milk during the second and third weeks after which a full ration of skim milk was fed in most instances until six months old. In addition to skim milk they had a dry mash of ground corn and oats, equal parts by weight, choice alfalfa hay, and a small amount of corn silage, the grain, hay, and silage being placed before them at ten days of age.

The calves in lot 2 were fed whole milk until five weeks of age, this being gradually replaced (beginning at seven days of age) by a home-mixed calf meal (containing hominy feed, linseed meal, red dog flour, and dried blood, equal parts by weight) mixed with water in the proportion of 1:7. Whole milk was fed to the calves that developed digestive disturbances or were otherwise off feed until the eleventh week. By the time the regular feeding of whole milk was discontinued the calves were getting from 18 to 20 oz. of the mixed meal per head daily, which amount was increased to 24 oz. by the time they were six months old. Otherwise this lot had the same feeds as lot 1.

Lot 3 received whole milk regularly until five weeks of age, this being gradually replaced by a proprietary calf meal beginning during the second week, the calf meal being gradually increased and mixed with water in accordance with directions of the manufacturers until they were receiving a full ration of 17 oz. per head daily at five weeks. This amount was increased to 22 oz.

at six months. Whole milk was fed frequently throughout the test when the calves were off feed. Otherwise this lot had the same feeds as lots 1 and 2.

Water and salt were before the calves at all times and particular care was used to insure a uniform temperature of the milk and milk substitute rations. Analyses are given of all the feeds used in the experiments.

The following table gives some of the results obtained:

*Calf feeding trials.*

Lot.	Birth weight.	Final weight.	Daily gain per calf.			Cost per pound of gain.	Total cost.	Average daily rations.				Nutritive ratio.
			Maximum.	Minimum.	Average.			Dry matter.	Crude protein.	Carbohydrates.	Fat.	
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Cts.</i>		<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	
1....	61.7	282.8	1.49	0.89	1.21	5.7	\$12.63	4.46	0.930	3.14	0.106	1:3.6
2....	69.6	244.1	1.39	.63	.95	7.4	12.93	4.15	.930	2.84	.165	1:3.4
3....	68.2	200.2	.95	.45	.73	13.1	17.44	3.45	.687	2.37	.189	1:4.0

Cost data in these experiments are based upon the following prices: Whole milk \$1.50 and skim milk 25 cts. per 100 lbs.; corn 60 cts. and oats 40 cts. per bushel; and alfalfa hay \$15, silage \$4, home-mixed calf meal \$40, and proprietary calf meal \$70 per ton.

The calves in lot 1 maintained a thrifty condition throughout the test, although considerable trouble was experienced by short attacks of indigestion or scours. The percentage cost of each feed for this lot was whole milk 15.5, skim milk 39.9, dry mash 16.38, alfalfa hay 27.07, and corn silage 1.15.

The calves in lot 2 did not present a thrifty appearance during the first part of the test. Indigestion caused a great deal of trouble, but this was usually checked by the substitution of whole milk for a part of the milk substitute. The calves' appetites were good after the eighth week. The percentage cost of this lot was whole milk 24.82, home-mixed calf meal 37.71, dry mash 13.76, alfalfa hay 23.04, and corn silage 0.67.

The calves in lot 3 were not very thrifty during the first part of the experiment, indigestion being the chief trouble in the majority of cases. This was usually remedied by the substitution of whole milk for a part of the proprietary calf meal. In two instances calves failed to recover from attacks of indigestion and lack of proper nutrition, one dying at the age of 40 days and the other at the age of 45 days. With one exception the remaining calves of this lot presented a thrifty condition at the end of the test. The percentage cost of each feed for this lot was whole milk 38.53, proprietary calf meal 39.16, dry mash 9.23, alfalfa hay 12.61, and corn silage 0.47.

Detailed consideration is presented of the variation in weight of calves, cost and amount of rations consumed, food nutrients received, and growth of the calves in each lot, together with a summary of the comparative efficiency of the various rations used in the experiments.

It is concluded that the use of skim milk for young calves, where it is available in large quantities, should be encouraged unless its market value is over 30 cts. per 100 lbs. Where the chief product sold from farms is whole milk "the use of a home-mixed calf meal is advisable, although the calf so produced will not be as well developed at 6 months of age as if fed milk during its early growing period.

"The prices charged by concerns manufacturing calf meals are usually very much above the actual cost of producing them, chiefly on account of advertising

cost, transportation charges, and dealers' profits. All things being equal so far as the efficiency of the ration is concerned, the use of a ready-prepared calf meal is largely prohibitive on account of the high retail prices of such feeds. . . .

"In order for a ration to be considered an unqualified success for dairy calves, it should produce at least 1 lb. of gain per day as an average for the first six months of the life of the calf. An average daily gain of 1.5 lbs. is not uncommon, although slightly above that which the average dairyman may expect.

"The amount of grain mixture and dry roughage consumed by dairy calves is a splendid index to their thriftiness. . . . The amount of food nutrients required per day by growing calves is approximately 0.33 lb. of protein, 1 lb. of carbohydrates, and 0.05 lb. of fat. The above figures are based upon the total amount rather than the amount of digestible nutrients consumed.

"The rate of growth in height of dairy calves is rather uniform during the first six months of their lives. The average monthly growth for an average sized calf should be from 1.5 to 2 in., although certain individuals may much exceed these figures. As dairy calves advance in age their relation between height and weight gradually changes. A calf at 30 days of age should weigh approximately 3 lbs. for each inch in height. This figure gradually increases until, at six months of age, the average calf should weigh approximately 6.5 lbs. for each inch in height."

The efficiency of certain milk substitutes in calf feeding, R. H. CARR, G. SPITZER, R. E. CALDWELL, and O. H. ANDERSON (*Jour. Biol. Chem.*, 28 (1917), No. 2, pp. 501-509, figs. 6).—Experiments conducted at the Indiana Experiment Station are reported, the objects of which were to determine to what extent a calf meal made up of both animal and vegetable feeding materials, rich in protein, could take the place of skim milk, and whether the proteins from wholly vegetable sources are capable of producing growth and development of the calf to the same extent as the proteins from animal sources.

Fresh separator skim milk was fed at 98° F. The calf meals were mixed with water (1:12 by weight) and fed at the rate of 4 oz. of dry meal at first to 12 oz. on full feed, the mash being fed at a temperature of 98°. The calves had a dry mash of equal parts of ground corn and oats, and alfalfa hay. A sample was taken from each meal at the time of mixing for chemical estimation of the nitrogen content, and from this the amount of nitrogen consumed daily was calculated. The meals used were mixed as follows: Vegetable meal—linseed meal, soy bean meal, cotton-seed meal, and wheat middlings (equal parts by weight); home-mixed meal—hominy feed, linseed meal, flour, and dried blood (equal parts by weight); vegetable-dried-blood meal—soy bean meal, linseed meal, cotton-seed meal, wheat middlings, and dried blood (equal parts by weight); and home-mixed casein meal—hominy feed, linseed meal, flour, and casein (9:9:9:8 by weight). Old-process linseed meal was used in these mixtures.

The feeding experiment in which 4 calves were used was divided into three periods of 29, 25, and 18 days each. The rations were changed for each period of the test, skim milk being fed for one period to each calf and one of the mixed meals to 2 calves for one period, so that each calf received skim milk and two of the mixed meals in the course of the experiment. Of the nitrogen consumed in the different rations the following percentages were retained: Skim milk 40.7, home mixed meal 32, home mixed casein meal 30, vegetable meal 27.3, and vegetable-dried-blood meal 22.6. The gains in grams of body weight per gram of nitrogen consumed for the different rations were skim milk 34.41, home mixed

casein meal ration 32.74, vegetable-dried-blood meal ration 26.85, home mixed meal ration 26.17, and vegetable meal ration 26.14. The nitrogen intake was rather constant per kilogram of body weight, the maximum difference being 12 per cent. It appeared that when the nitrogen in the ration was the most suitable for growth the nitrogen excreted was about equally divided between the feces and the urine.

Sheep feeding.—VI, Fattening western lambs, 1915-16, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul.* 192 (1916), pp. 20; pop. ed., pp. 7).—In these experiments, which are in continuation of those already noted (E. S. R., 35, p. 476), nine lots of 25 lambs each were fed for 100 days, eight of the lots being fed in open sheds and one lot in the barn. The lambs were choice improved Mexicans of excellent quality. The rations fed, in addition to shelled corn, and some of the results obtained are given in the following table:

Lamb feeding trials.

Lot.	Ration, in addition to shelled corn.	Feed consumed per pound of gain.			Average daily gain per head.	Cost per pound of gain.	Final value of lamb per pound.	Profit per lamb.
		Grain.	Dry roughage.	Silage.				
		Lbs.	Lbs.	Lbs.	Lbs.	Cts.	Cts.	
1	Cottonseed meal and corn silage.....	5.48	0.58	10.77	0.175	8.86	10.05	\$0.80
2	Cottonseed meal, molasses, clover, and corn silage.....	3.99	4.64	4.35	.256	8.49	10.40	1.29
3	Clover hay.....	4.19	7.57	.....	.24	8.81	10.20	1.02
4	Alfalfa hay.....	3.87	6.55	.....	.26	7.87	10.75	1.74
5	Cottonseed meal, corn silage, and oat straw.....	5.78	3.63	7.37	.172	9.11	9.65	.46
6	Corn silage and clover hay.....	4.07	4.74	4.52	.247	8.00	10.30	1.31
7	Cottonseed meal, corn silage, and clover hay.....	4.00	4.65	4.45	.252	8.26	10.90	1.74
8	Ground soy beans, corn silage, and clover hay.....	4.14	4.78	4.61	.243	8.52	10.65	1.45
9	Corn silage and clover hay fed in barn..	4.22	4.91	4.57	.239	8.27	10.30	1.22
	Average.....	4.33	4.86	4.18	.232	8.42	10.37	1.23

In a comparison of corn silage *v.* corn silage and clover hay for fattening lambs, involving lots 3 and 6, it was found that the addition of silage to a ration of shelled corn and clover hay had no effect on the grain consumption, but that 112 lbs. of silage replaced 65 pounds of clover hay in roughage consumption. Comparing corn silage alone *v.* corn silage and dry roughage, involving lots 1, 5, and 7, it was found that with the elimination of dry roughage from the ration there was a decrease in grain consumption and an increase in silage consumption. When oat straw was fed in connection with silage more corn was required to produce a pound of gain than when either silage alone or silage and clover hay were fed.

In a comparison of clover hay and alfalfa hay, involving lots 3 and 4, the hay consumption was higher when clover was fed, and the finish on the lambs better when alfalfa was fed. In this test the clover hay was slightly moldy and the alfalfa hay of excellent quality. The addition of cottonseed meal at the rate of 3 lbs. per day for 25 lambs to a ration of shelled corn, clover hay, and corn silage, involving lots 6 and 7, had no effect on the daily feed consumption, but apparently gave a much better finish to the lambs. In substituting a small quantity of cane molasses for an equal quantity of corn in a ration of shelled corn, cottonseed meal, clover hay, and silage, involving lots 2 and 7, no marked effects on the appetites or finish of the lambs were noted.

Ground soy beans and cottonseed meal were compared as supplements, involving lots 7 and 8. The appetites of both lots were equally good, but the results slightly favored cottonseed meal. In a comparison of open shed *v.* barn as shelter for fattening lambs, involving lots 6 and 9, no difference was found in grain or hay consumption of the two lots. Silage consumption was slightly greater in the open shed, this being due to the fact that these lambs learned to relish silage sooner than those in the barn.

Other data in reference to comparisons of feeds and shelter are given in the above table.

The cost of gains and profits were based on the following figures: Initial value of lambs 8.85 cts. per pound; corn, first month 47.2, second month 54.8, third month 61.7, and last 10 days 64 cts. per bushel; oats (a small quantity of which was used in accustoming lambs to rations) 32 cts. per bushel; and cottonseed meal and ground soy beans \$38, molasses \$30, clover and alfalfa hay \$12, oat straw \$5, and corn silage \$4.50 per ton.

**Ewes' milk: Its fat content and relation to the growth of lambs,** E. G. RITZMAN (*U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 2, pp. 29-36, fig. 1*).—Data are reported on this subject from the New Hampshire Experiment Station, covering six distinct breeds and including native sheep and 11 types of first-generation crosses of sheep which may be considered as nonmilk breeds.

The fat content of 158 samples of ewes' milk taken at approximately one month after lambing varied from 2.4 to 12.1 per cent, the average being 6 per cent. Averages are given for the breeds and crosses for different age periods. These averages are practically equal for any age period from two to seven years, varying from 5.3 per cent at seven years to 6.38 per cent at five years. Wide variation was found in the fat content of samples of milk from the first, second, and third lactation periods of individual ewes. The average fat content of all the samples from 46 ewes was for the first year 5.67 per cent, second year 6.03 per cent, and third year 5.81 per cent.

A study was made of the growth of suckling lambs of 138 ewes whose milk varied in fat content from 2 to 10 per cent. The highest gains, 37 lbs., were made from milk testing from 2 to 3 per cent fat and the lowest gains, 18 lbs., from milk testing 10 per cent or over. On elimination of these extreme cases the fluctuation in weight increase bore no relation to the fat content of the milk. The limiting factor for growth in these tests was apparently the quantity of milk. Based on close observation, verified by the actual amounts of milk drawn for the determination of fat, these 138 ewes were classified according to milk yield as high, good, fair, and poor. The average weights of the lambs of these classes were at 4 weeks 14.7, 13.4, 10.8, and 8 lbs.; at 8 weeks 34, 29.3, 24.6, and 19 lbs.; at 12 weeks 50.2, 43.3, 35.4, and 30 lbs.; and at 16 weeks 60.7, 55.3, 45.4, and 39 lbs., respectively. All the lambs had free access to a liberal amount of grain and hay which they ate greedily after they were about 8 weeks of age.

A list of the literature cited is given.

**Feeding pure-bred draft fillies,** J. L. EDMONDS (*Illinois Sta. Bul. 192 (1916), pp. 426-448, figs. 18*).—In this experiment 10 pure-bred Percheron fillies were fed from weanlings to two years of age to determine the efficiency of alfalfa hay, corn, and oats. The experiment began December 8, 1914, and ended when the fillies were turned on pasture May 8, 1916, thus covering two winter and one summer feeding periods. Oats and corn were fed, one-half of each by weight, with alfalfa hay as the sole roughage. During the first winter the oats and corn were ground, and after that whole oats and shelled corn were fed. The pasture was a blue-grass sod, containing a slight mixture of other grasses. Analyses are given of the grain and hay used in the experiment.

Except during the first 28 days, when the fillies were allowed as much grain and hay as they would consume, the grain was restricted in amount so that the hay eaten amounted to 1 lb. or more daily per 100 lbs. of live weight.

The results indicated that a liberal proportion of well-cured legume hay should be the foundation for feeding young growing horses, and that enough grain should be fed to produce good growth. It is also indicated that as the individual becomes older the proportion of grain to hay may be decreased and still obtain good gains. In this experiment 0.5 lb. of grain daily per 100 lbs. of live weight was sufficient for proper development except for a short time when the pasturage was scant.

The average daily gain per head during the first winter was 1.94 lbs., during the summer 0.85 lb., and during the second winter 1.22 lbs., or 1.33 lbs. for the 518 days. The total gain per head was 690.5 lbs. and the average increase in height 7.96 in. The average total feed consumed during the whole experiment was 45.35 bu. of corn, 79.36 bu. of oats, 2.58 tons of alfalfa, and 0.8 acre of pasture per head. The average amount of feed required to produce a pound of gain was during the first winter 5.67 lbs. of grain and 4.27 lbs. of hay, and during the second winter 9.23 lbs. of grain and 13 lbs. of hay. The average weight of the fillies at one year was 1,112 lbs. and at two years 1,548 lbs.

On the basis of \$11 per ton for alfalfa hay, 50 cts. per bushel for corn, 35 cts. per bushel for oats, and \$10 per acre for pasture, the cost per pound of gain was 7.98 cts. for the first winter, 16.04 cts. for the summer, and 16.31 cts. for the second winter. On the same price basis the average total cost of feed per head was \$56.07 for the year and \$86.88 for the year and five months.

**Fourth annual international egg laying contest, W. F. KIRKPATRICK and L. E. CARD** (*Connecticut Storrs Sta. Bul.* 87 (1916), pp. 197-244, figs. 25).—In experimental pens in connection with this contest skim milk was substituted for the beef and fish scrap in the regular ration. Fifty hens on the regular ration laid 7,380 eggs and 50 hens on the milk ration laid 8,359 eggs. The milk-fed hens consumed 2,000 qt. of milk, valued at \$20, and those on the regular ration about 350 lbs. of beef and fish scrap, at a cost of \$9.

In the main contest the Rhode Island Red eggs averaged 1.6 lbs. per dozen, Plymouth Rock eggs 1.56 lbs., White Leghorn eggs 1.52 lbs., Wyandotte eggs 1.47 lbs., and miscellaneous breeds, including Light Brahmas, American Dominiques, Brown, Buff, and Black Leghorns, Silver Campines, Light Sussex, Salmon Faverolles, White Orpingtons, and Buttercups, 1.56 lbs. The average weight of the eggs for all of the breeds was 1.54 lbs. per dozen. The percentages of broody hens averaged from 5.9 for the White Leghorns to 69.6 for the Wyandottes, the average for all breeds being 37.2. The average number of days lost each broody period was 20.6. The number of eggs laid per month by the 1,000 hens in this contest varied from 4,070 in November to 18,280 in May. Over 34 per cent of the total eggs for the year were produced in March, April, and May.

In the operation of trap nests the number of eggs laid outside the nests varied from 8 in a pen of Orpingtons to 140 in a pen of Wyandottes, the average percentage of unidentified eggs for all the breeds being 3.73. Weight curves showed that all breeds were heaviest on March 1, and, with the exception of the first weighing on November 1, they were lightest on May 1.

The 1,820 birds involved in the third (E. S. R., 33, p. 672) and the fourth contests consumed an annual average of 44.4 lbs. of grain per hen or about 2 oz. per day. The feed cost per dozen eggs in the fourth contest was 12.7 cts. for the Leghorns, 12.9 cts. for the Wyandottes, 15.3 cts. for the Rhode Island Reds, and 16.2 cts. for the Plymouth Rocks, the average for all breeds being

14 cts. per dozen. In this contest it required an average of 4.27 lbs. of mash and grain to produce 1 lb. of eggs. Data with reference to egg production, feed, temperature, etc., are tabulated.

How to operate an incubator, J. E. DOUGHERTY (*California Sta. Circ. 156* (1916), pp. 8, figs. 3).—Detailed directions are given.

### DAIRY FARMING—DAIRYING.

Journal of the British Dairy Farmers' Association (*Jour. Brit. Dairy Farmers' Assoc.*, 30 (1916), pp. 257, figs. 7).—This contains articles by various authors on milk recording in Great Britain, milk substitutes for calves, dairying of the future, dairying in New Zealand, fluctuations in the fat content of milk, the world's progress in dairying, the milking trials of 1915, and other dairying topics.

Twenty-sixth, twenty-seventh, twenty-eighth, and twenty-ninth annual reports of the Bernese Dairy School at Rütli-Zollikofen, A. PETER ET AL. (*Jahresber. Molk. Schule Rütli-Zollikofen*, 26 (1912-13), pp. 70, pl. 1; 27 (1913-14), pp. 58, pl. 1, figs. 3; 28 (1914-15), pp. 100, pl. 1; 29 (1915-16), pp. 88, figs. 7).—These are the usual reports (E. S. R., 28, p. 372).

The first-named also includes a discussion of the preparation of rennet, analytical data on the examination of milk by determination of the refractive index, analytical data obtained by the examination of milk by determining the specific gravity of the calcium chlorid serum, and the results of tests of a number of mechanical appliances.

The second report gives the results of some tests with a mechanical butter machine, a practical cheese test with a commercial coagulant, the use of fish meal as a feed for swine in conjunction with dairy waste, and the separation of cream by centrifugation.

The third report contains experimental results on the use of aluminum containers and the calculation of the food value of dairy waste in the feeding of swine.

The last report contains experimental work on the detection of milk adulteration by watering and analysis of butter and the results of tests of a number of mechanical appliances used in the dairy industry.

Experiments in the feeding of dairy cows, J. DUNLOP and P. W. BAILEY (*Midland Agr. and Dairy Col., Rpt. Expts. Feeding Dairy Cows* [1916], pp. 16).—In each of the three experiments here reported, each of which lasted for six weeks, eight Shorthorn cows were fed by the reversal system. The first and fourth weeks of each experiment were allowed for the cows to become accustomed to the rations.

In a comparison of hemp-seed cake and linseed cake the cows were fed a basal ration of cabbage, hay, straw, mixed grain, and Egyptian cotton-seed cake. In addition they received either 4 lbs. of linseed cake or 4 lbs. of hemp-seed cake per head daily. During the four weeks of the experiment proper the cows on linseed meal gained 58 lbs. in weight and produced 2,043.5 lbs. of milk, containing 3.8 per cent of fat. On hemp-seed meal they gained 4 lbs. in weight and produced 2,073 lbs. of milk, containing 3.75 per cent of fat. There was no difference in churnability of the milk or in flavor of the butter in favor of either of the rations. The hemp-seed cake had a slightly constipating effect upon the cows.

In a test comparing dried yeast with decorticated cotton-seed meal the cows were fed the same basal ration as in the above test and in addition either 3 lbs. of dried yeast or 3 lbs. of decorticated cotton-seed meal per head daily. On the dried yeast ration the cows gained 56 lbs. in weight and produced

2,954.75 lbs. of milk containing 3.77 per cent of fat. On the cotton-seed meal ration they gained 120 lbs. in weight and produced 2,913.5 lbs. of milk containing 3.72 per cent of fat. There was no difference in churnability of the milk or in flavor and quantity of the butter in favor of either of the rations, except that the butter made during the feeding of cotton-seed meal was the harder and of a better color.

In a test comparing decorticated peanut cake with decorticated cottonseed cake the cows were fed a basal ration of mangels, hay, bran, and dried yeast, and in addition either 4 lbs. of peanut cake or 4 lbs. of cottonseed cake. On peanut cake the cows lost 51 lbs. in weight and produced 3,504.25 lbs. of milk containing 3.86 per cent of fat; and on cottonseed cake they gained 111 lbs. in weight and produced 3,437.25 lbs. of milk containing 3.97 per cent of fat. There was no difference in quality or flavor of the butter from either of the rations, except that the butter churned during the peanut ration period was the softer.

Analyses of each of the concentrates compared in these tests are given.

The raising of dairy heifers, R. R. KERR (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 7, pp. 385-397, figs. 6).—In addition to general directions for and notes on raising dairy heifers, results are given of tests of heifers conducted by the government in Victoria. It is stated that the results of these tests are showing not only the value of breeding and care of animals and their productive qualities, but are furnishing the basis for a list of sires showing consistent dairy heredity.

Dairying in Uruguay, A. ABELLA (*Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 5, pp. 629-637).—Brief data are given on the number of dairy cattle, milk production and consumption, butter and cheese making, the importation of dairy products, dairy regulations, and cooperation in milk production in Uruguay.

The milk problem, J. J. DILON ([*Utica, N. Y.: Dairymen's League*], 1916, pp. 16.)—This is an address delivered at Utica, N. Y., on September 16, 1916, on the economic conditions surrounding the sale and distribution of milk in New York City and State.

The milk supply of Paris by producers' associations, M. DONON (*L'approvisionnement en Lait de la Ville de Paris par les Associations de Producteurs. Orléans: Imprimerie Oriéanaise*, 1914, pp. 170, figs. 29).—This manual deals briefly with the milk supply and consumption of Paris, the price of milk to producers, conditions governing the sale of milk, milk syndicates, the organization and operation of cooperative dairies, and the production of hygienic milk. Appendixes give model constitutions of milk syndicates and cooperative dairies, rules governing the collecting of milk, estimates and specifications for the installation of equipment for cooperative dairies, and illustrations of plans and machinery.

[Proceedings ninth and tenth annual conferences of the American Association of Medical Milk Commissions, 1915 and 1916] (*Proc. Amer. Assoc. Med. Milk Com.*, 9 (1915), pp. 210; 10 (1916), pp. 256).—These reports give, respectively, the proceedings of the ninth annual conference of this association, held at San Francisco, Cal., June 17-19, 1915, and the tenth annual conference, held at Cincinnati, Ohio, June 9-11, 1916. Reports of various medical milk commissions, the constitution and by-laws of the association, a list of medical milk commissions in the United States and Canada, and papers by various authors on the production of sanitary milk are included. The proceedings for the tenth conference also contain methods and standards for the production and distribution of certified milk.

**Bacteriological examination of the Bombay milk supply, L. L. JOSHI** (*Jour. Dairying [India]*, 3 (1915), No. 1, pp. 5-36, fig. 1).—This paper discusses the sources of bacteria in milk, factors influencing the multiplication of bacteria in milk, tubercle bacilli in milk, bacterial standards for milk in India, and methods and results of the bacteriological examination of a number of samples of buffaloes' and cows' milk from various sources in Bombay.

The average number of bacteria in 240 samples of milk bought at random from dairies, milk shops, cattle stables, railway stations, individual milk vendors, etc., in Bombay from April, 1913, to July, 1914, was 36,385,000 per cubic centimeter. A number of samples of milk collected under strict precautions from healthy cows and buffaloes and examined immediately gave an average bacteria count of 292 per cubic centimeter, and the tests for lactose fermenters and pathogenic microbes were negative in all cases. Out of 741 samples of Bombay milk examined during four years no tubercle bacilli were found. These results have since been confirmed at the Bombay bacteriological laboratory and the author concludes that tuberculosis is rarely, if at all, conveyed by milk in India.

**Essentials for the production of clean milk, W. J. DOUGAN** (*Hoard's Dairyman*, 1916, Dec. 22, pp. 757, 788, figs. 6).—This is a brief discussion of the essentials for the production of high-class milk at reasonable prices.

**Cooling milk on the farm, H. F. JUDKINS** (*Coun. Agr. Col. Ext. Serv. Bul.* 1 (1916), pp. 18, figs. 4).—General directions are given for cooling milk on the farm, including the use of the cooling tank, milk coolers, and mechanical refrigeration, and the cooling of bottled milk.

**Some aspects of the physiology of milk secretion, R. L. HILL** (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 4, pp. 483-510).—This is a brief survey of the theories and scientific investigations upon this subject, and an account of recent experiments upon the increase of milk secretion due to the injection of substances present in the pituitary body. A list of the literature reviewed is given.

**Rapid method of counting bacteria in milk, W. D. FROST** (*Science, n. ser.*, 42 (1915), No. 1077, pp. 255, 256).—This outlines a rapid method of counting bacteria in milk described below.

**A rapid method of counting living bacteria in milk and other richly seeded materials, W. D. FROST** (*Jour. Amer. Med. Assoc.*, 66 (1916), No. 12, pp. 889, 890, figs. 5).—This paper describes in detail the method noted in the preceding abstract. In brief the method is as follows:

One-twentieth cc. of milk is mixed with standard nutrient agar and spread over a definite area of a sterile glass slide. When the agar is hard, this little plate culture is put in the incubator for about six hours under conditions which prevent evaporation. It is then dried, given a preliminary treatment to prevent the agar from firmly binding the stain, stained, decolorized, and cleared. When this dried and stained plate culture is viewed under the microscope, the little colonies are definitely stained and appear highly colored on a colorless or slightly colored background. These colonies can be readily counted and the number of bacteria per cubic centimeter calculated.

The author states that this method can be used for pasteurized milk, but in case of recently pasteurized and very good milks the time required for incubating the plates will probably be from 8 to 12 hours.

**Counting bacteria in milk in less than eight hours, W. D. FROST** (*Milk Dealer*, 6 (1916), No. 3, pp. 24-32, 34, 36, figs. 11).—The author reviews the various attempts that have been made to devise a method for the bacteriological examination of milk in a shorter time than that required for the plate method, and gives results obtained by the method noted above. Charts are also given of a number of series of comparative tests showing the variation in bacteria

counts of samples of milk by the rapid method and by the standard plate method.

In one series the ratio of the standard plate counts to the rapid plate counts varied from 1:0.05 to 1:7.43 with an average of 1:0.96. In nearly two-thirds of the counts the rapid method gave a lower count than the standard method. In another series the ratio varied from 1:0.02 to 1:2.8 with an average of 1:1.17. Tests by other experimenters are reviewed which show that variations occurring between duplicate plates or between different dilutions in the same sample by the ordinary plate method are often as great as the above.

A brief description is also given of a microscopic test for pasteurized milk which has been noted from another source (E. S. R., 34, p. 113), and results obtained with about 500 samples of milk tested by this method are noted. The author claims that by this method not only freshly pasteurized milk but pasteurized milk that has become recontaminated can be readily detected.

A list of cited literature is given.

**Comparison of a rapid method of counting bacteria in milk with the standard plate method.** W. D. FROST (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 273-287, figs. 6).—The method here described and the data reported have been noted from another source (see above).

**Points in butter factory management under home separation.** G. M. VALENTINE (*Jour. Agr. [New Zeal.]*, 13 (1916), No. 1, pp. 17-25).—This paper deals with the problems that arise in the management of gathered-cream butter factories, including weighing, sampling, and testing cream; neutralizing and pasteurizing; cooling and refrigeration; power; churning and moisture testing; and the keeping of records.

**A practical guide for the manufacture of butter and cheese.** A. DE TOTH (*Guia Practica de la Fabricacion de Mantequilla y Quesos*. [Mexico City]: Sec. Fomento, Colon. e Indus., 1916, pp. 164, figs. 65).—General directions are given for making cheese and butter under Mexico conditions.

**Various experiments in making Cheddar cheese.** L. BIBEAU (*Rpt. Dairymen's Asso. Prov. Quebec*, 34 (1915), pp. 222-230).—Brief results are given of cheese making experiments conducted by the author at various dairy schools and cheese factories in Quebec during 1914 and 1915.

## VETERINARY MEDICINE.

**Practical bacteriology, blood work, and animal parasitology.** E. R. STITT (*Philadelphia: P. Blakiston's Son & Co.*, 1916, 4. ed., rev. and enl., pp. XVII+497, figs. 119).—This is the fourth edition of the work previously noted (E. S. R., 26, p. 174). Because of the rapid advances in the subject practically every chapter has been revised and new material added. Portions of some chapters have been entirely rewritten. A new chapter dealing with diseases of unknown or doubtful origin has been added, in which is discussed the vitamin theory in beriberi and pellagra, as well as recent findings in typhus fever, rat-bite fever, Rocky Mountain spotted fever, etc.

Bacteriological keys, zoological tables, explanatory clinical notes, and an appendix giving directions for the preparation of tissues for examination in microscopic sections, the mounting and preservation of animal parasites, the preparation of normal solutions, and the chemical examination of blood, urine, gastric contents, and duodenal fluid, and a brief discussion of disinfectants and insecticides are included.

**The packing for shipment of meat samples for bacteriological examination.** L. FILENSKI (*Arb. K. Gsndhtsamt.*, 50 (1915), No. 1, pp. 133-148).—Data submitted show that meat samples to be sent for bacteriological examination

can be satisfactorily packed in bran. For larger samples wrapping in cotton cloth previously soaked in alcohol is recommended. The use of vinegar, mercuric chlorid, pickling solutions, borax, and bleaching powder is not recommended as practical, although in isolated cases the experimental results obtained were satisfactory.

**Serums, vaccines, and toxins in treatment and diagnosis**, W. C. BOSANQUET and J. W. H. EYRE (*New York: Funk & Wagnalls Co., 1916, 3. ed., pp. VIII+456, figs. 20*).—This volume discusses the subject under the general topics of immunity and resistance to disease, preparation and administration of sera and bacterial vaccines, sera and toxins in diagnosis, diphtheria, tetanus, snake bite, hydrophobia, smallpox and vaccinia, anthrax and glanders, plague, cholera, enteric fever, dysentery and other bacillary infections, tuberculosis, leprosy, affections due to streptococci, other infections due to cocci, catarrhal affections, diseases due to protozoa, and malignant tumors. An appendix on various conditions treated with sera is included.

**Digested and diluted serum as a substitute for broth for bacteriological purposes**, A. DISTASO (*Brit. Med. Jour., No. 2912 (1916), pp. 555, 556*).—The author describes the preparation of a culture medium from sheep or ox serum by digestion overnight with an aqueous extract of pig's pancreas previously activated with an aqueous extract of a small portion of the duodenum of the pig.

A luxuriant growth of the *Bacillus coli* group, streptococcus, staphylococcus, *B. subtilis*, *B. proteus*, and *B. fluorescens* was obtained on the medium. Little or no growth of meningococci was obtained, however.

For indol formation the medium yielded the same results as the usual tryptophane medium. The medium is also suited for sugar tests and by combining with agar can be used to produce a beautiful transparent solid medium.

Directions for the preparation of the diluted serum for sugar tests are also submitted. This medium is especially suitable for *B. coli* and is much cheaper than those commonly used.

**The effects of serum treated with agar**, E. ZUNZ and M. GELAT (*Jour. Expt. Med., 24 (1916), No. 3, pp. 247-269*).—Experiments reported in detail show that the intravenous injection into normal rabbits of horse serum, previously kept for two hours at 38° C. in the presence of 0.2 of its volume of a 0.5 per cent suspension of agar in physiological saline and then separated from the agar by centrifugalization and filtration, produces a considerable and prolonged fall in blood pressure, expulsion of feces, diminished coagulability in the carotid blood, and, at times, accelerated respiration. The various symptoms produced are the same as those observed after the intravenous injection of horse serum into a previously sensitized rabbit.

Horse serum previously kept for 30 minutes at 56°, and then treated with agar as described, produces no other effect than does the ordinary introduction of horse serum into the veins of a normal rabbit.

The experimental results are discussed in some detail.

**The effect of moderately high atmospheric temperatures upon the formation of agglutinins**, C. E. A. WINSLOW, J. A. MILLER, and W. C. NOBLE (*Proc. Soc. Expt. Biol. and Med., 13 (1916), No. 8, pp. 194-197*).—The results of experiments reported, in which animals were immunized by successive intraperitoneal injections of increasing doses of killed typhoid bacilli and kept at temperatures ranging from 29 to 32° C., indicate that the moderately high temperatures tend to lower the power of agglutinin formation in rabbits.

**Immunity produced by intravascular injections**, L. CAMUS (*Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 14, pp. 338-340*).—Experiments are reported which show that the time necessary for immunization varies with the dose of vaccine employed. It is not possible, as some have supposed, to suppress the

latent phase (incubation period), but the time can be controlled by increasing or decreasing the quantity of vaccine used. The importance of individual variation in the production of immunity is noted.

**Studies on antibodies.**—I, Analyses and nitrogen distribution of a number of antisera, E. J. BANZHAF, K. SUGIURA, and K. G. FALK (*Jour. Immunol.*, 2 (1916), No. 1, pp. 125-135).—This material has been previously noted (E. S. R., 36, p. 80).

Experiments with oil of *Chenopodium* and cardiac stimulants on the isolated frog heart, W. SALANT and A. E. LIVINGSTON (*Amer. Jour. Physiol.*, 41 (1916), No. 1, pp. 21-38, figs. 10).

A further report on thromboplastin solution as a hemostatic, A. F. HESS (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 24, pp. 1717-1720).—A number of cases are reported in which an aqueous extract of ox brain was successfully used.

It is concluded that the thromboplastin is of practical value in controlling hemorrhage wherever it can reach the site of bleeding. In cases of true hemophilia it may be regarded almost as a specific hemostatic. Its use is indicated in a variety of hemorrhages. In cases where local applications fail the thromboplastin solution should be injected into the site of hemorrhage. This procedure can be readily resorted to as the solution loses little of its potency as the result of dilution and rapid boiling.

In addition to its hemostatic action the extract was found to possess healing properties, actively stimulating granulation and hastening epithelization.

**Spontaneous amebic dysentery in monkeys**, A. EICHHORN and B. GALLAGHER (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 395-407, figs. 5).—This paper reports upon a spontaneous outbreak of a disease in monkeys in which the lesions corresponded closely to those found in amebic or tropical dysentery in man, and in which protozoal organisms occurred that had the structure and characteristics of those amebas generally considered the causative agents in human tropical dysentery.

**The presence of *Bacillus typhosus* in the blood of rabbits after inoculation into the gall bladder**, LANGE and ROOS (*Arb. K. Gsndhtsamst.*, 50 (1915), No. 1, pp. 57-95).—In a very short time after inoculation of typhoid bacilli into the gall bladder of rabbits the presence of the organisms can be detected in the blood of the ear vein. This migration takes place directly at the point of inoculation or in the immediate tissue through the blood capillaries of the gall bladder. Such a rapid migration does not take place from other organs which are equally as rich in capillaries. Injection of bile into the gall bladder facilitates the migration, while the subcutaneous injection inhibits it. By direct injection into the liver a similar migration takes place. The animals which have been inoculated in the gall bladder with the organisms become carriers of the organisms, whether the migration was slow or rapid. Where the gall bladder was extirpated shortly after the inoculation (six minutes) the animals did not become carriers.

In one animal typhoid bacilli were found in the urine 20 minutes after inoculation.

**The etiology of Rocky Mountain spotted fever**, S. B. WOLBACH (*Jour. Med. Research*, 34 (1916), No. 1, pp. 121-126, pl. 1).—The author reports the occurrence of a bacterium in large numbers in the lesions characteristic of spotted fever in experimental animals. "The organism corresponds in some respects with the description given by Ricketts of bodies which he found in the blood of human and experimental cases, and in the tissues and eggs of infected ticks. The classification of the organisms is not yet clear; of its bacillary form and multiplication by transverse division there can be no question."

**The etiology of Rocky Mountain spotted fever.**—Occurrence of the parasite in the tick, S. B. WOLBACH (*Jour. Med. Research*, 35 (1916), No. 158, pp. 147-150).—"A parasite has been found in proved infected ticks in large numbers, morphologically identical with the parasite found in the lesions of guinea pigs and monkeys infected with Rocky Mountain spotted fever. This parasite does not occur in the tissues of ticks proved to be noninfective.

"The distribution of the parasite in the infected ticks indicates that the transmission occurs by way of the salivary gland secretions. Transmission by fecal contamination of the wound caused by the tick does not seem possible because of the character of the tick's feces."

**Equine and bovine streptococci as causal agents of human infections**, A. J. CHALMERS and A. MARSHALL (*Jour. Trop. Med. and Hyg.* [London], 19 (1916), Nos. 18, pp. 213-215; 19, pp. 225-228).—The authors here attempt to trace the pathogenic streptococci found in puerperal fever and in sore throats to their sources.

**The occurrence in the United States of certain nematodes of ruminants transmissible to man**, B. H. RANSOM (*New Orleans Med. and Surg. Jour.*, 69 (1916), No. 4, pp. 294-298).—In this article the author calls attention to the occurrence in this country of three of the four species of *Trichostrongylus* which have been recorded as parasites of man, namely, *T. colubriformis*, *T. vitrinus*, and *T. probolurus*, reference to which has previously been noted (E. S. R., 25, p. 387).

**Some notes on the encysted larva of the lung distome**, S. YOSHIDA (*Jour. Parasitology*, 2 (1916), No. 4, pp. 175-180, fig. 1).—This further paper on the subject (E. S. R., 35, p. 384) reports some of the results obtained in a subsequent study on the cysts of the lung distome in crabs, especially *Eriocheir japonicus*.

**Immunity studies on anthrax serum**, A. EICHHORN, W. N. BERG, and R. A. KELSER (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 2, pp. 37-56, fig. 1).—The authors have fractionated anthrax serum obtained by the hyperimmunization technique previously described by the senior author (E. S. R., 34, p. 579) by the methods commonly used in the fractionation of diphtheria antitoxin. The anthrax antibodies were found in the pseudoglobulin fraction. The globulin preparations contained the antibodies in a concentrated form, as shown by numerous tests on laboratory animals. Tests on larger animals also proved the presence of antibodies in this preparation. Preliminary data obtained from the use of the serum and globulin in the treatment of anthrax in man showed it to yield very satisfactory results.

The methods of analysis of serum and similar preparations with some slight modifications and improvements are described in detail. For the separation of globulin precipitates from their filtrates centrifugalization has been found to be more effective and rapid than filtration.

Experiments to determine the changes in the serum proteins during immunization (mule) showed a pronounced rise in the content of total coagulable protein and total globulin, as has been noted by other investigators immunizing against diphtheria, tetanus, and rinderpest virus.

The value of a preparation as described, in that a much smaller dose is required which may be safely inoculated intravenously and also as minimizing the danger of anaphylactic shock, is pointed out. The complement-fixation test has been applied to the standardization of the anthrax serum, and while it is considered still to be in an experimental stage its value as an accurate method of standardization is indicated.

The analytical and immunization data are submitted in tabular and graphical form.

**Simultaneous vaccination against blackleg**, F. S. SCHOENLEBER (*Amer. Jour. Vet. Med.*, 11 (1916), No. 10, pp. 796, 797).—The use of a blackleg serum (filtered sterile serum of highly immunized animals) on 2,500 head of calves with practically no loss is reported. The serum is said to have not only protected the animals against the disease but checked it when given in the early stages. The immunity, however, lasts only a few days, so that the administration of the serum must be followed by an inoculation of the virus. As much as 300 cc. has been introduced intramuscularly into one animal without any serious effects.

**Serological investigational methods as aids in the diagnosis of trypanosome diseases, with special reference to dourine**, R. OFFERMANN (*Arb. K. Gsndtsamt.*, 50 (1915), No. 1, pp. 1-30).—The results of the study reported show that sera obtained from healthy rabbits in many cases were antihemolytic. The regularity of the occurrence of this antihemolytic property could not be established. In the use of rabbit serum in complement-fixation tests it is indicated that the serum should be tested before inoculation.

Agglutinins which will agglutinate the trypanosomes of dourine were not found in normal rabbit serum. Complement-binding antibodies and agglutinins, however, were found in the sera of rabbits which had previously been inoculated with the trypanosomes. The antibodies did not always appear simultaneously. In general, complement-binding amboceptors were detected earlier than agglutinins. The time of appearance and quantity of antibodies varied with the individual animals and with the course of the disease. The quantity diminished somewhat in the course of the disease but increased again in time. No regularity of this phenomenon could be established. In no case did they disappear completely from the blood stream.

Antibodies could be detected in the serum kept under sterile conditions after many months.

For agglutination it is stated that a fresh suspension of trypanosomes must be used. The antigen used for complement fixation was found to retain its activity for many weeks if kept in a refrigerator.

Complement fixation and agglutination are considered to be valuable diagnostic aids. Since complement fixation yields more satisfactory results it is to be preferred.

**Foot-and-mouth disease**, A. VRIJBURG (*Tijdschr. Diergeneesk.*, 43 (1916), No. 22, pp. 847-865).—This discusses the subject under the topics of virus; virus carriers; spread of the disease through negligence in handling diseased animals and carcasses, through wild animals, insects, wind, waterfowl, etc.; clinical symptoms; severe forms of the disease; differential diagnosis; susceptibility; immunity; sanitary and hygienic measures; immune serum; immunization with attenuated virus; and simultaneous treatment.

**Foot-and-mouth disease**, E. M. MULDER (*Tijdschr. Diergeneesk.*, 43 (1916), No. 22, pp. 838-847).—This is a general discussion of the disease from the standpoint of control and eradication.

The author considers that the virus of the disease produces a lasting immunity in the animals, as is evidenced by the natural immunity of the offspring. A system of immunization of all male animals which are to be used for breeding purposes is outlined and is considered to be the most rational method for eradicating the disease.

**Foot-and-mouth disease in Friesland**, H. VAN STAA (*Tijdschr. Diergeneesk.*, 43 (1916), No. 22, pp. 825-837, figs. 2).—This is a general review and discussion of the outbreaks of the disease from 1891 through 1915.

The data presented show that the outbreaks of the disease during the months of October, November, December, January, February, and March were twice as

great as during the remaining or summer months. The virus of the disease is believed to have been introduced, even from the first outbreak, by infected water-fowl, which come into the country from the east in the fall of the year.

It is indicated that more infectious diseases are carried by birds than is usually considered.

Old and new methods for the diagnosis of glanders, E. GRÄUB (*Schweiz. Arch. Tierheilk.*, 58 (1916), No. 11, pp. 579-595, figs. 2).—This is a general discussion of the various biological methods used in the diagnosis of glanders.

The conglutination reaction is described and discussed in some detail.

Diagnosis of tuberculosis by complement fixation, with special reference to bovine tuberculosis, A. EICHHORN and A. BLUMBERG (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 1, pp. 1-20, fig. 1).—A brief historical résumé is given and the preparation of antigens and data obtained in their standardization submitted. An antigen prepared with bacillary emulsion and tuberculin precipitate was found to be the most effective in the serological tests.

From data obtained with the use of these antigens with 816 bovine, 120 porcine, and 22 human sera, it is concluded that the complement-fixation test in cattle is not so reliable as the subcutaneous tuberculin test. Since a large proportion of the positive cases give only a faint reaction, a very careful titration of the antigen and a most accurate observance of all the details of the technique of the test are necessary. The degree of the reaction could not be considered as an index to the extent of infection. It is thought that the test could be employed as a supplementary test in cases of doubtful or atypical reactions to the subcutaneous or other allergic tests, but it is not deemed practical for general diagnostic purposes.

The results of the test are affected by subcutaneous injection of tuberculin into healthy animals. This interference may be noted as early as the fourth day following the injection, and may persist for six weeks, or possibly for a much longer time.

A list of 43 references of cited literature is appended.

The diagnosis of tuberculosis with special reference to the intrapalpebral test, N. MORI (*Ann. Staz. Sper. Malattie Infet. Bestiame, R. Ist. Incoragg. Napoli*, 2 (1914), No. 2, pp. 289-317).—Experimental data obtained by the use of the various procedures for the introduction of tuberculin into suspected animals (bovines) are reported in detail and discussed.

It is concluded that the intrapalpebral test is a reliable and easily manipulated procedure for the diagnosis of tuberculosis, especially in general practice.

Transmission of porcine tuberculosis to man and the reinoculation of calves, H. MARKUS (*Rev. Gén. Méd. Vét.*, 25 (1916), No. 298, pp. 466-478, figs. 3).—The case of a veterinarian infected with the tubercle bacillus through a small abrasion on the thumb during the examination of a large number of tuberculous hogs is reported.

The micro-organism was isolated from the wound and after cultivation injected into calves. The disease was produced in all cases and the diagnosis substantiated by post-mortem findings. The bacteriological, histological, and autopsical findings are described.

It is indicated that the case demonstrates that the bacillus of Koch coming from the hog is equally pathogenic for the human organism.

Bovine tuberculosis, J. G. WILLS and C. LINCX (*N. Y. Dept. Agr. Bul.* 82 (1916), pp. 1875-1956, figs. 34).—This bulletin discusses the subject under the general topics of tuberculosis and its development, dissemination of tuberculosis, tuberculosis in calves, tuberculin, reactions, physical examinations, pasteurization, and methods of control. A glossary of terms relating to the subject is included.

Cases of poisoning in cattle by feeding on meal from soy bean after extraction of the oil, S. STOCKMAN (*Jour. Compar. Path. and Ther.*, 29 (1916), No. 2, pp. 95-107).—A report of deaths among cows receiving a ration of soy bean meal or cake in a district in the south of Scotland in which 54 of 67 affected cows on nine different farms died led to an investigation of the cause. The symptoms and post-mortem appearances are described and data collected on eight of the farms are reported in tabular form. With these data as a basis, laboratory feeding experiments were conducted with cattle and other animals and are here reported.

The feeding of extracted soy cake and meal produced symptoms and post-mortem lesions which were identical with those occurring in the field among cattle fed on similar material. The extracted soy in no case, in practice or laboratory, produced a sudden effect, considerable amounts being consumed and a considerable time elapsing before signs of illness appeared. The smallest amount consumed at the laboratory before the disease appeared was 172 lbs. in 36 days. The shortest time in which the disease appeared was 29 days, during which period 201 lbs. were fed. No animal other than cattle suffered from feeding on this meal or cake, either in practice or at the laboratory.

It is pointed out that the very high temperature (106 to 109° F.) accompanying the illness seems to exclude the ordinary poisons but does not exclude a poison of the ricin class. Specific bacterial infection was excluded by test inoculations, microscopical and bacteriological examinations, and by the sterilizing temperature which was used in the process of manufacture. No castor seeds could be traced in the meal.

A wide inquiry shows that the whole soy bean is not poisonous and an inquiry among manufacturers shows that there is plenty of evidence that soy extracted with naphtha does not cause poisoning; thus it appears that the trouble was caused by the use only of soy extracted with trichlorethylene, although this is not poisonous when given to cattle in from 1 to 3 oz. and for long periods. It is suggested (1) that the products from trichlorethylene obtained by heat may be poisonous, (2) that the trichlorethylene in contact with soy and heat to drive off the former may form a poison, or (3) that some of the trichlorethylene was impure and contained other bodies. Thus it is inadvisable to use trichlorethylene as an extractor.

A disease resembling "forage poisoning" in horses and mules wherein oat hay incorporated the primary factor, R. GRAHAM, L. R. HIMMELBERGER, and R. L. PONTIUS (*Rept. U. S. Live Stock Sanit. Assoc.*, 19 (1915), pp. 22-42, figs. 2).—Previously noted from another source (*E. S. R.*, 34, p. 681). See also a note by Graham and Himmelberger (*E. S. R.*, 36, p. 280).

Studies on forage poisoning, R. GRAHAM and L. R. HIMMELBERGER (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 385-394, figs. 3).—The first part of this paper (pp. 385-388), which deals with the pathologic changes in a disease in horses resembling forage poisoning, is based upon studies of tissues secured from seven horses fatally affected in consequence of feeding on an oat hay in the experiments above noted. "While the pathologic presentations in the various tissues examined are not diagnostic, since no pathognomonic importance can be ascribed to them, the changes found collectively are suggestive of a toxemialike condition in so far as the type of the disease we have studied is concerned."

The second part of the paper (pp. 388-394) relates to a pathogenic bacillus, isolated from the same oat hay as was the *Bacillus coli*-like organism above noted, which grew readily under laboratory conditions. Feeding and inoculation experiments indicate that the bacillus is nonpathogenic for rabbits, guinea pigs, white rats, chickens, cats, dogs, and swine. Horses, mules, cattle, sheep, and goats do not succumb to a single intravenous injection, except in rare instances,

but repeated daily injections in horses are followed by nervous manifestations, marasmus, coma, and death. "The symptoms observed in experimental horses following the injection of the sterile filtrate of this bacillus grown on Uschinsky's medium evidence the production of a toxinlike substance as an inherent character of the bacillus isolated from the oat hay, and the results from repeated administrations suggest a systemic cumulative action. Repeated intravenous injections of the bacillus washed from agar slants, sterile filtrates of the culture on Uschinsky's medium, broth cultures by way of the mouth or in the form of enemas produced variable nervous symptoms and death in horses and mules."

"A somewhat similar microorganism has been isolated from the chicken excreta found in the oat hay, but its pathogenicity has not yet been established. This micro-organism was not isolated from two apparently wholesome forages examined bacteriologically, but from sorghum silage obtained from a farm where animal fatalities had occurred with symptoms resembling forage poisoning, a micro-organism with somewhat similar cultural characteristics was obtained. The micro-organism from the sorghum silage possesses pathogenic properties, as observed following inoculation of experimental horses," and reported below.

Studies in forage poisoning, R. GRAHAM and L. R. HIMMELBERGER (*Jour. Compar. Path. and Ther.*, 29 (1916), No. 2, pp. 107-116).—In continuation of the above studies, the authors report upon an outbreak in Woodford County, Ky., in December, 1915, in which losses occurred among young cattle fed grain rations and silage. The symptoms in these animals consisted of emaciation, dull languid appearance, incoordination in walking, loss of appetite, diarrhea, decubitus, temperature and respiration normal, and pulse weak. The feeding of the silage, which consisted of sorghum cut about one week before placing it in the silo in August, was discontinued, and no further losses occurred.

Fourteen experiments with animals, including cattle, horses, sheep, and goats, were made, in which feeding and inoculation tests were carried out with silage, watery extract of silage, cultures of the bacillus, and sterile filtrates from cultures. The bacillus isolated from the silage, but which could not be found in the station sorghum silage, possessed pathogenic properties for some of the experimental animals. "Daily administrations of sterile filtrates of this bacillus grown on a synthetic medium, introduced intrajugularly, and bouillon cultures in the form of enemas produced death in horses, as did also daily drenches of bouillon cultures to calves, with clinical manifestations and gross anatomical changes not unlike those observed in some cases of forage poisoning. The morphological and cultural features of this bacillus are in every major detail analogous to those possessed by a pathogenic organism isolated from an oat hay responsible for losses among horses and mules, as demonstrated by feeding experiments," as noted above.

The etiology of infectious anemia of the horse, CARRÉ and VALLÉE (*Rec. Méd. Vét.*, 92 (1916), No. 7, pp. 193-199; *Ann. Inst. Pasteur*, 30 (1916), No. 8, pp. 383-388; *abs. in Trop. Vet. Bul.*, 4 (1916), No. 3, pp. 124, 125).—This is a summary of work conducted by the authors during the past 12 years, with references to the work of others who have confirmed the authors' original findings incriminating an ultraviolet virus as the cause of this disease. The authors refuse to admit the unicity of pernicious anemia of the horse and that the disease is only verminous in origin, as reported by Seyderhelm and Seyderhelm (*E. S. R.*, 33, p. 681) and by Ries (*E. S. R.*, 18, p. 584).

Report on the investigation into joint-ill in foals existing in the Province of Ontario, F. W. SCHOFIELD (*Toronto, Canada: Govt.*, 1915, pp. 16).—This first report includes tables giving the bacteriological results in 23 cases of joint-ill and the results of vaccine treatment. A specially prepared bacterial vaccine containing *Staphylococcus aureus*, *Streptococcus* sp., and *Bacillus abortivus*-

*equinus* was tested in 170 cases and found to be followed by a decrease in the mortality of more than 50 per cent.

Second report on the investigation into joint-ill in foals existing in the Province of Ontario, F. W. SCHOFIELD (*Toronto, Canada: Govt., 1916, pp. 24, figs. 5*).—The investigations here reported, in continuation of those above noted, have led to the following conclusions:

“The disease joint-ill can be prevented in many cases by the use of a suitable prophylactic vaccine. The vaccine used in this experiment, while producing results that are far from ideal, was of definite prophylactic value. The treatment has no untoward effect upon the foal either immediate or delayed. The vaccine should be used in conjunction with the other prophylactic measures in combating this disease. . . . Better results are obtained from the use of vaccines in the treatment of joint-ill than from any other method of treatment. There is much room for improvement as the average mortality is still far in excess of what it should be. . . .

“A hemolytic streptococcus is apparently very closely related to the disease joint-ill. Marked pathogenicity for the rabbit is characteristic of the hemolytic streptococcus of joint-ill. In some of the most severe cases, no organisms could be isolated from the joint fluid or blood. Ingestion infection is quite probable since the presence of streptococci has been found in the milk of the dam identical with those recovered from the diseased joints of foals.”

A nongas-producing strain of the hog-cholera bacillus isolated from an old laboratory culture, C. TENBROECK (*Jour. Expt. Med., 24 (1916), No. 3, pp. 213-222*).—“In a stock culture of the hog-cholera bacillus, which was passed through a series of rabbits 14 years ago, an organism was found that differs from the original culture in that it fails to form gas from the carbohydrates that are usually attacked by this organism, while acid formation persists. This new strain is agglutinated by an antihog-cholera bacillus serum, and produces in rabbits and mice a disease similar to that caused by the typical cultures. The failure to form gas has persisted over a period of 18 months, and all attempts to cause the strain to revert to the original condition have failed.”

The organism resembles in many respects *Bacillus typhosus*. Attempts to produce a similar change in more recently isolated cultures by animal passages and changes in environment failed.

## RURAL ENGINEERING.

Seventeenth biennial report of the state engineer, Colorado, 1913-14, (*Bien. Rpt. State Engin. Colo., 17 (1913-14), pts. 1, pp. 261, pl. 1; 2, pp. 350*).—This report includes data on the general irrigation situation in Colorado, including financial matters, gives abstracts of reports of the water commissioners, reports the results of numerous seepage investigations, and gives the results of measurements of flow made in the Arkansas, Grand, Laramie, Rio Grande, San Juan, South Platte, Yampa, and White river drainage basins.

Surface water supply of Pacific drainage basins in Washington and upper Columbia River basin, 1914 (*U. S. Geol. Survey, Water-Supply Paper 392 (1916), pp. 7-200, pls. 2*).—This report, prepared in cooperation with the States of Washington, Montana, and Idaho, contains the results of measurements of flow made on streams in the Puget Sound and the upper Columbia River drainage basins.

Profile surveys in Skagit River basin, Washington (*U. S. Geol. Survey, Water-Supply Paper 419 (1916), pp. 5-8, pls. 12*).—This report, prepared under the direction of W. H. Herron, contains a plan and profile of Skagit River and certain tributaries above Concrete, Wash., made from surveys in 1915.

Profile surveys along Henrys Fork, Idaho, and Logan River and Blacksmith Fork, Utah (*U. S. Geol. Survey, Water-Supply Paper 420 (1916), pp. 5-8, pls. 10*).—This report, prepared under the direction of W. H. Herron, describes the general features of the Snake River basin and the Logan River basin and gives plans and profiles of Henrys Fork above St. Anthony, of the outlet of Henrys Lake, Idaho, of Logan River above Logan, and of Blacksmith Fork, above Hyrum, Utah.

Profile surveys in 1915 along the Rio Grande, Pecos River, and Mora River, in New Mexico (*U. S. Geol. Survey, Water-Supply Paper 421 (1916), pp. 5-11, pls. 11*).—This report, prepared under the direction of W. H. Herron, contains plans and profiles from surveys made in 1915 of the Rio Grande in the vicinity of Buckman, N. Mex., and from Embudo, N. Mex., to the Colorado state line, of the Pecos River above Alexander Valle Grant, N. Mex., and of the Mora River from its mouth to the east boundary of Mora Grant, N. Mex.

Irrigation field laboratory at Denver, Colorado, R. B. SLEIGHT (*Engin. News, 76 (1916), No. 23, pp. 1080-1082, figs. 5*).—This laboratory, which is part of the equipment of the Irrigation Investigations Division of the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture, is described and some of the important features illustrated.

Concrete pipe irrigation systems (*Jour. Electricity, 37 (1916), No. 12, pp. 219-221, figs. 6*).—The manufacture of concrete pipe for use in irrigation distribution systems is discussed, and diagrams are given showing the carrying capacity in cubic feet per second, miners' inches, and gallons per minute of concrete pipe varying in diameter from 6 to 24 in. and with a slope varying from 0.5 to 30 ft. per 1,000 ft. The value of  $n$  in Kutter's formula used is 0.0135.

[Competitive tests of (commercial) overhead irrigation systems in 1914]. E. KRÜGER and A. NACHTWEH (*Arb. Deut. Landw. Gesell., No. 276 (1915), pp. 87, figs. 55*).—This paper includes a general discussion of irrigation and irrigation systems and a description of overhead irrigation systems with prices. It also reports tests of four commercial types of overhead irrigation systems.

Malheur and Owyhee projects, irrigation and drainage, J. T. WHISTLER and J. H. LEWIS (*Oreg. Cooper. Work, Dept. Int. U. S. Reclamation Serv., 1916, Feb., pp. XII+13-201, pls. 52, fig. 1*).—This report, prepared in cooperation with the State of Oregon, gives the results of investigations for the irrigation from the Malheur River of Malheur Valley lands in the vicinity of Vale and Ontario, Oreg., and of lands in the vicinity of Nyssa from the Owyhee River.

"The Malheur project includes approximately 39,150 acres of irrigable land, of which approximately 31,600 acres are the first development and 7,550 acres a later extension of the first development. . . . The present plans are to use the river as the main distributary. . . .

"An agricultural and soil survey of the lands under the proposed project shows the fertility of the lands and at the same time the necessity for drainage. The long seasons and fertility of the soil make it capable of fairly intensive development. . . . The duty adopted for the gravity lands is 2.6 ft. in depth during the irrigating season; for the pump lands 2.1 ft. in depth for the season. The distribution losses are estimated at 20 per cent of the water taken out at the heads of the laterals. The seepage loss for earth sections is estimated at 1 ft. in depth per day over the wetted area of canals and for concrete lined canals 1 in. in depth. . . . The yearly diversion use for the development of the full project or 39,150 acres is 161,400 acre feet. . . . The reservoir capacity required is 159,000 acre-feet. . . . The total cost of the entire project, including drainage, is \$1,438,458, an average cost of approximately \$37 per acre. . . .

"The development proposed in the Owyhee Project is the irrigation of about 18,100 acres of land lying partly on both sides of Owyhee River in the vicinity of Mitchell Butte, and in addition the inclusion within the project of about 4,900 acres now served from the Ontario-Nyssa Canal (Shoestring Ditch), which derives its supply for irrigation use by pumping from Snake River. . . . A soil and agricultural survey of the area included within the project . . . shows that this area is capable of a fairly intensive cultivation and is as promising as any arid soil in the State which is susceptible of reclamation by irrigation. . . . The duty of water adopted for the lands of this project is 2.6 ft. in depth during the irrigating season for the lands under the main gravity canal on the north side of the river and on the lands served from the Ontario-Nyssa Canal. The corresponding duty for all the other lands of the project is 2.1 ft. in depth. Distribution losses are estimated at 20 per cent of the water delivered to the heads of laterals. Canal seepage losses from the heads of laterals to the diversion are estimated at 1 ft. in depth per day over the wetted canal area for unlined canal sections, and similarly 1 in. in depth for lined sections. . . . The cost of the Owyhee Project is estimated at approximately \$1,446,000; including capitalization for operation, maintenance, and renewal of pumping plants, and for maintenance of siphons."

**Flood relief for the Scioto Valley [Ohio], 1916, J. W. ALVORD and C. B. BURDICK** (*Columbus, Ohio: State, 1916, pp. [XII]+279, pls. 36, figs. 32*).—This report includes the recommendations of the chief engineers for the adoption of the official plan of two detaining basins, "one each on the Scioto above Dublin and the Olentangy above Delaware and channel improvements for the 200,000 second-foot project, costing all told the sum of \$10,125,000."

**Preliminary report on Kearney Vineyard experimental drain, W. W. WEIR** (*California Sta. Bul. 273 (1916), pp. 103-123, figs. 11*).—This report, prepared in cooperation with the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture, deals with the drainage of an unproductive quarter section of alkali land, which was originally a vineyard.

The soil consists of sandy loam and fine sandy loam, and the alkali content varied in the surface foot from less than 0.2 per cent over most of the tract to 3 per cent over small areas. The principal salts were sodium chlorid and sodium carbonate, with the former predominating. "Observations taken during 1912 and the early part of 1913 showed that at no time during the year was the water table more than 7.5 ft. below the surface, and during June it stood within 2 ft. of the surface. During the entire growing season the water was less than 6 ft. from the surface and for four and one-half months was less than 4 ft. below the surface."

The drainage system installed consists of 21,842 ft. of drain, varying in size from 6 to 12 in. tile. The main drain has a fall of 1 in 1,000 and an average depth of about 7 ft. "The lateral system, consisting of eight parallel laterals on the east and nine on the west side of the main, is composed of 6-in. tile at an average depth of 5.75 ft. The laterals are 315 ft. apart." The total cost of the drain was \$59.59 per acre.

"From measurements taken of the pump discharge it is evident that drainage systems under similar conditions should be designed to remove at least 1 cu. ft. per second for each 100 acres, especially where the drained tract is entirely surrounded by undrained land. Indications are that the lateral drains might have been placed 400 ft. apart. It would have been better had the lateral tile lines been placed 6.5 or 7 ft. deep instead of 5.75 ft. The hardpan, which was known to exist, has not proved to be a material hindrance to the movement of water.

"Two years' flooding has been sufficient to reduce the alkali present to an amount which is considered safe for crops. The tests show that although there was originally nearly two and one-half times as much NaCl as Na<sub>2</sub>CO<sub>3</sub> in the surface foot of soil this salt is much more easily removed by flooding than the Na<sub>2</sub>CO<sub>3</sub>, and although the latter has been reduced by 15 per cent there was, at the end of the second year, more than one and one-half times as much Na<sub>2</sub>CO<sub>3</sub> as NaCl in the surface foot of soil. . . . The tract has been changed, after three years, from that previously described to one producing a crop of 180 tons of grain hay in 1916."

**Velocity coefficients for a dredged drainage canal, P. V. HODGES** (*Engin. News*, 76 (1916), No. 22, pp. 1052, 1053, figs. 6).—Tests of the application of different formulas to the flow of water in a drainage canal 25 miles long, excavated by a  $\frac{3}{4}$  cu. yd. dipper dredge in peat soil underlain with clay, are reported.

It was found by current meter measurements at two sections that the coefficient  $n$  of Kutter's formula varied from 0.0253 to 0.0259, and the velocity as computed with these values had a variation of 2.5 per cent within the range of this experiment. The coefficient  $m$  of Bazin's formula,  $V = \frac{87}{0.552 + \frac{m}{\sqrt{R}}} \sqrt{RS}$

varied from 1.127 to 1.164, and the velocity as computed with these values had a variation of 2 per cent. The coefficient  $C$  in the exponential formula  $V = CR^{0.67} S^{0.54}$  varied 4 per cent. To obtain a formula that applies more closely to the law of flow in this canal, the formula  $V = K(RS)^{0.58}$  was derived, in which  $K = 229.6$ . The value of the coefficient  $K$  varied 1.8 per cent within the range of this experiment.

The value of  $n$  was found to decrease as the velocity or hydraulic radius increased, the condition of the channel remaining the same.

**Reduction of seepage losses in a canal through porous shale, J. H. MINER** (*Reclam. Rec. [U. S.]*, 7 (1916), No. 12, pp. 568-570, fig. 1).—Experiments conducted on canals of the Grand Valley Irrigation Project showed the favorable influence of artificial silting of canals in markedly reducing conveyance losses.

"The protective measures adopted consisted in excavating the canal through shale to a depth of 1 ft. below the required grade, with a view of allowing silt to accumulate in this extra depth. . . . Part of the earth lining was placed before water was turned into the canal and part afterwards. The work done with the water in the canal was the more effective in that the material compacted better and more quickly and also spread farther out on the canal bottom."

**Care and attention necessary for maintenance of metal flumes, F. D. PYLE** (*Reclam. Rec. [U. S.]*, 7 (1916), No. 11, pp. 519, 520; *rev. in Engin. Rec.*, 74 (1916), No. 21, p. 622).—Experiments with seven paint and tar mixtures, including African black, Egyptian black, elastic graphite, green graphite, tar compound, coal tar, and green paint when used as preservatives for metal flumes on the Uncompahgre Project, are reported.

It was found "that the coal tar, coal-tar compound, and elastic graphite were the only mixtures that could stand one season's use, and there was some doubt as to the elastic graphite standing another season. It appears from observations on this project and the observations of project managers on other projects that coal tar is the best and cheapest mixture available. In some instances a first coat of water gas tar has been applied before the coal tar with excellent results. In tarring flumes care should be exercised to clean the surface thoroughly. All joints should be carefully tarred. It may be advisable to hot dip all sheets before they are placed in the flume."

Rectangular wooden flumes, J. C. STEVENS (*Engin. News*, 76 (1916), No. 25, pp. 1160-1162, fig. 1).—"The object of this article is to touch briefly on a few important points, connected with the design and construction of wooden flumes for irrigation and power purposes, that have not been treated either in textbooks or in technical articles."

Method of making drainage and improvement assessments, P. A. CUPPER (*Engin. News*, 76 (1916), No. 21, pp. 975, 976).—Suggestions for appraisal work in drainage and similar improvement districts are given.

The hygiene of water, A. GÄRTNER (*Die Hygiene des Wassers*. Brunswick: Friedrich Vieweg & Son, 1915, pp. 952, pls. 11, figs. 93; abs. in *Ztschr. Angew. Chem.*, 29 (1916), No. 17, *Wirtschaftlicher Teil*, pp. 141, 142).—This is a handbook for engineers, waterworks superintendents, chemists, and medical officials. It deals with the sanitary aspects of domestic and other water supplies and with the chemistry and bacteriology of drinking water in general. Features of water-supply systems and apparatus are also dealt with.

Disinfection of drinking water by the successive action of sodium hypochlorite and hydrogen peroxid, E. DOYEN and TODA (*Compt. Rend. Soc. Biol. [Paris]*, 79 (1916), No. 6, pp. 232, 233; abs. in *Chem. Abs.*, 10 (1916), No. 19, p. 2487).—Experiments on the treatment of sterilized, distilled river and lake water to which 24-hour cultures of *Bacillus coli* and Eberth bacillus were added in a minimum amount of 20,000 per cubic centimeter are reported.

Labarraque solution containing 7.45 gm. of sodium hypochlorite (equivalent to 3.55 gm. of chlorin) per liter and officinal hydrogen peroxid containing 34 gm. hydrogen peroxid per liter were employed. When the Labarraque solution was used in an amount corresponding to 1 mg. of chlorin per liter of water, the water was sterilized in one minute. It is recommended, however, that an amount equivalent to 3 mg. of chlorin per liter of water be used, and that sufficient hydrogen peroxid be added at the end of five minutes to cause the evolution of all the oxygen of the sodium hypochlorite. Impure water treated successively with sodium hypochlorite and hydrogen peroxid was more palatable than that treated with sodium hypochlorite and sodium hyposulphate. The sterilizing action was also much more effective in the former than in the latter case. It is noted that the hydrogen peroxid used had no appreciable bactericidal action.

Laboratory manual of bituminous materials, P. HUBBARD (*New York: John Wiley & Sons*, 1916, pp. XI+153, figs. 39; rev. in *Engin. Rec.*, 74 (1916), No. 26, p. 778).—This manual is primarily intended as a laboratory guide for students and others, its object being to describe methods in sufficient detail to enable the performance of the more common and widely used tests with a reasonable degree of accuracy. It is divided into three parts.

Part 1 gives general information on definitions of materials, tests, and uses; types and classification of bituminous materials, especially those for road and paving use; refining processes; and laboratory methods. Part 2, methods of testing, covers tests for density, consistency, and solubility of other than bituminous aggregates; heat tests; miscellaneous tests; and the extraction of bituminous aggregates and recovery of bitumen and aggregate. Part 3, characteristics of the more important bituminous materials, deals with fluid petroleum products and emulsions, semisolid and solid petroleum and asphalt products, refined tars and tar pitches, creosoting oils or wood preservatives, and bituminous aggregates.

Road material surveys in 1914, L. REINECKE (*Canada Dept. Mines, Geol. Survey Mem.* 85 (1916), pp. VIII+244, pls. 7, figs. 16).—This report is published in four parts.

Part 1 is a description of the various kinds of country roads, of the materials used in their construction, of the different varieties of stone outcropping at the surface of the earth, and of their comparative value as road-making materials.

Part 2 is a description of certain large deposits of diabase upon the north shore of Lake Huron. Part 3 is a report on road materials in Essex and Kent counties, Ontario, and Part 4 is a report on road materials along a portion of the north shore of Lake Ontario.

Reinforcement for concrete roads, J. R. CHAMBERLIN (*Cement Era*, 14 (1916), No. 11, p. 44).—A mathematical analysis of the stresses in concrete roads leads to the conclusion "that that type of reinforcement would be most efficient whose cross sectional area multiplied by the cube of the cosine of the angle between the reinforcing member and a line transverse to the roadway is a maximum."

Some factors in the Indiana road problem, G. E. MARTIN (*Purdue Univ. Dept. Engin., Highway Bul. 2* (1916), pp. 27, figs. 19).—This is a summary and discussion of the various factors affecting the road problem in Indiana, including road mileage, topography, climate, soil, road materials, population, area, traffic, and finance.

Report of the [Iowa] State Highway Commission for the year ended December 1, 1915 (*Ann. Rpt. Iowa Highway Com., 2* (1915), pp. 221, figs. 55).—This report deals with the organization, administration, road and bridge construction work, expenditures, and technical investigations during 1915.

Among other technical investigations one year of service tests on highway bridge paints brought out the following tentative results: "First, as a class the coal-tar paints are forming alligator cracks, but as yet are giving good protection, with a single exception. The coal-tar paint which has been exposed the longest time has more or less completely broken down, and there is evidence of rusting beneath the paint film. Second, the asphalt paints are cracking and checking on the approach of cold weather. There is yet no evidence of rusting of the iron underneath. Third, the red leads in general, especially where there is a large amount of inert material mixed in the pigment, are fading badly, and in some cases checking, chalking, and cracking. This fact would point to the recommendation that red lead paint be used in connection with a covering coat of a more stable paint. These paints are in general wearing better than the coal-tar or asphalt paints. Fourth, the sublimed white leads are as a rule wearing well. There is some evidence of checking. Fifth, the sublimed blue leads are in general wearing better than any of the other lead paints. Sixth, the best grades of iron-oxid paints are standing out exceptionally well, while the iron-oxid paints which contain calcium sulphate or calcium carbonate are showing signs of dissolution, leaving pit holes in the paint film. Seventh, where the graphite and carbon paints are placed next to the iron there are marked indications of corrosion or rusting. When used as a second coat over a prime coat of first quality iron oxid or lead these paints appear to be very serviceable. Eighth, the paints containing the highly inhibitive pigment, zinc chromate or lead chromate, are standing the service tests exceptionally well.

"The results thus far are such as to substantiate the requirements of the standard specifications for paint of the Highway Commission. In general, the paints which can be admitted under these specifications are wearing well, while those which would be excluded under these specifications are proving to be inferior in wearing quality and serviceability."

Third annual report of the State Highway Commission of the State of Maine (*Ann. Rpt. Highway Com. Maine, 3* (1915), pp. 195, fig. 1).—This is a report of the work and expenditures on highway construction, maintenance, and repair in Maine from January 1 to December 31, 1915.

How to run the gas engine—simplified, L. ST. JOHN (*New York: Manhattan Electric Supply Co., 1915, 4. ed., pp. 55, figs. 3*).—This is a handbook for gas engine owners, tractioners, and motorists.

Truck and tractor engines, H. L. HORNING (*Gas Engine*, 18 (1916), No. 12, pp. 590-600, figs. 3).—This paper deals with "first, the demands made on modern truck and tractor engines; second, the most serious problems the engineer has met in fulfilling the demands; and third, the lines the development of the future is likely to take." Fuel and features of design receive special attention.

Exhibition trial of motor tillage implements (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 28 (1916), pp. 281-296, figs. 5; *abs. in Jour. Bd. Agr. [London]*, 23 (1916), No. 6, pp. 600, 601).—This is a detailed report of trials previously noted (*E. S. R.*, 34, p. 788).

[Special tests of tractors, 1915], M. RINGELMANN (*Bul. Mens. Off. Renseig. Agr. [Paris]*, 14 (1915), pp. 1176-1182).—Tests of seven American tractors when traveling without load and when on mechanical cultivation, including draft tests, are reported. The more important results of the tests over soil without load are given in the following table:

*Tests of tractors without load.*

Calculated horsepower.	Condition of wheel rims.	Average speed per hour.	Fuel consumption per ton km.	State of soil.	Slip of driven wheels.
		Meters.	Kilogram.		Per cent.
7	Corners and projections.....	5,354	0.88		
9	Calks.....	5,148	.39	Slippery.....	3.0
19	Corners and projections.....	3,748	.28	Very slippery.....	6.3
17	Calks.....	5,364	.74	Dry.....	1.5
22	Fixed projections.....	2,232	.35	Slippery.....	3.0
22	Projections and pointed arches.....	3,276	.30	Very dry.....	.5
	Smooth.....	4,608	.24	Dry.....	1.5
26	Strips.....	3,060	.34	After rain.....	3.0
	Strips and pointed arches.....	3,060	.33	do.....	2.5
	Corners.....	3,240	.36	Sound.....	.5

The more important results of mechanical plowing tests are given in the following table:

*Mechanical plowing tests.*

Calculated horsepower.	Plowing depth.	Plowing width.	Distance plowed per hour.	Area plowed per hour.	Fuel consumption per hectare.	Average draft per square decimeter plowed.	Average horsepower utilized at drawbar.	Value of coefficient. <sup>m</sup>
					Kg.	Kg.	Hp.	
7.....	<i>Cm.</i> 3.5	<i>Meters.</i> 1.00	4,572	3,157	11.2	64.2	3.74	0.40

<sup>m</sup>In the equation  $t = mP$ , in which  $t$  = average draft and  $P$  = drive-wheel pressure on the soil.

Public tests of mechanical cultivating apparatus in 1916, P. BUCHARD (*Vie Agr. et Rurale*, 6 (1916), No. 41, pp. 260-269, figs. 6).—This report reviews the more important results of mechanical plowing tests made at five different

localities in France during 1916. The machines tested included tractors, motor plows, and motor cultivators.

Mechanical cultivation, R. DESSAISAIX (*Jour. Agr. Prat., n. ser., 29 (1916), No. 20, pp. 341, 342*).—The more important results of plowing tests on hard, dry, calcareous clay soil at Tours, France, with six tractors are given in the following table:

*Tractor plowing tests.*

Horse-power.	Number of plow bottoms.	Average depth of plowing.	Surface plowed per hour.	Volume of soil plowed per hour.	Fuel consumption.	
					Per cubic meter of soil plowed.	Per hectare plowed 0.16 meter deep.
		<i>Meters.</i>	<i>Square meters.</i>	<i>Cubic meters.</i>	<i>Liters.</i>	<i>Liters.</i>
8-16.....	2	0.158	1,972.60	311.67	0.0275	44.00
8-16.....	2	.166	1,931.42	320.61	.0260	41.60
12-24.....	3	.146	1,864.51	272.21	.0276	41.76
12-20.....	3	.173	2,847.76	492.60	.0180	28.80
12-20.....	2	.193	2,623.41	507.47	.0140	22.40
8-16.....	2	.151	2,035.20	307.31	.0300	48.00

The more important results of plowing tests with four tractors on tenacious calcareous clay soil containing hills with grades of from 10 to 16 per cent are summarized as follows:

*Tractor tests on hilly soil.*

Horse-power.	Soil.	Number of plows.	Width of plowing.	Average depth of plowing.	Average speed per hour.	Area plowed in 10 hours.	Fuel consumption per hectare.
			<i>Meters.</i>	<i>Cm.</i>	<i>Meters.</i>	<i>Hectares.</i>	<i>Liters.</i>
15	Level and hilly.....	2	0.52	16.6	3,200	1.2	52.7
15	.....do.....	1	.33	19.0	3,000	.9	70.0
16	Level.....	2	.57	18.0	3,600	1.3	50.0
16	Level and hilly.....	2	.70	14.5	3,600	1.6	56.0
20	.....do.....	3	.98	20.0	2,800	2.0	40.0

Report on demonstrations with motor tractors at York, 1915, J. GILCHRIST (*Univ. Leeds and Yorkshire Council Agr. Ed. [Pamphlet], 100 (1916), pp. 24, figs. 8; abs. in Jour. Bd. Agr. [London], 23 (1916), No. 6, p. 600*).—The general results of one-hour plowing tests on medium loam and uniform sandy loam soils with six internal-combustion tractors ranging in brake horsepower from 16 to 40, one 22-brake horsepower steam tractor, and a 10-horsepower motor plow are reported. The number of furrows plowed at one time varied from two to four.

Motor plows and motor plowing, A. AMOS (*Jour. Roy. Agr. Soc. England, 76 (1915), pp. 74-91; abs. in Jour. Bd. Agr. [London], 23 (1916), No. 6, pp. 599, 600*).—The use of the motor plow to meet war time conditions in England is discussed, and general information is given regarding the organization, cost, and economy of motor plowing.

Engine plows, I. A. WEAVER (*Trans. Amer. Soc. Agr. Engin., 9 (1915), No. 1, pp. 104-109, figs. 4*).—This is a discussion of the more important factors entering into the design of engine plows.

Experiments on mechanical cultivation at Grignon, F. BERTHAULT (*Ann. École Nat. Agr. Grignon, 5 (1914), pp. 5-205, figs. 14*).—This is a detailed report of controlled experiments on mechanical cultivation at Grignon during 1913-14, giving results and conclusions.

**N. G. E. A.** data sheets compiled by H. R. BRATE (*Lakemont, N. Y.: Nat. Gas Engine Assoc., 1916, pp. [310], figs. 10*).—Seven volumes of these data sheets are presented to date, as follows: Volume 1, National Gas Engine Association standards and general engineering data; volume 2, silage cutters; volume 3, feed grinders, grinders and crushers, buhr stone, and corn and cob crushers; volume 4, hay presses; volume 5, pumps; volume 6, electrical outfits; and volume 7, tractors.

**Markets for agricultural implements and machinery in Argentina**, F. H. VON MOTZ (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 125 (1916), pp. 86*).—This report gives detailed information regarding the market requirements of Argentina for all kinds of farm machinery, supplemented by data on agricultural conditions and trade methods.

**Diagram for obtaining number feet B. M. in various timbers**, W. R. ROOF (*Engin. and Contract., 46 (1916), No. 21, p. 453, fig. 1*).—A diagram is given which affords a convenient method for obtaining the number of feet board measure for various sizes of timber.

**The preservative treatment of farm timbers**, E. A. STERLING (*Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul. 3 (1916), pp. 17, figs. 6*).—This bulletin deals with preservatives, methods of treatment, preparing timber for treatment, kinds of timber suitable for treatment, conditions requiring treatment, and the cost.

**New roofing materials for rural structures**, R. DE SAINT-MAURICE (*Vie Agr. et Rurale, 5 (1915), No. 1, pp. 9-13, figs. 9*).—This describes and illustrates and gives working data regarding five different types of composition roofing and zinc roofing, special reference being made to their use on farm buildings in France.

**Grain storage buildings**, K. J. T. EKBLAW (*Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul. 2 (1916), pp. 16, figs. 3*).—This bulletin deals with the features of construction of grain-storage buildings, including the foundation, pressure on walls, floors, framing, walls, roof, and general arrangement, and describes and illustrates a small granary, a small corn crib, and a large grain-storage building.

**Swine houses**, K. J. T. EKBLAW (*Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul. 4 (1916), pp. 22, figs. 6*).—This bulletin points out the essentials of a good swine house and describes and diagrammatically illustrates small portable houses and large permanent houses.

**Dairy buildings at United States Naval Academy**, C. D. FRANCIS (*Hoard's Dairyman, 52 (1916), No. 21, pp. 725, 744, fig. 1*).—A brief description is given of the dairy buildings which are being constructed for the accommodation of about 200 cows on the dairy farm of the U. S. Naval Academy near Annapolis, Md.

**Shedding for milch cows on Rhodesian farms**, R. C. SIMMONS (*Rhodesia Agr. Jour., 13 (1916), No. 5, pp. 678-684, pl. 1*).—A permanent milch cow shelter of brick, thatch, and hardwood poles is described and diagrammatically illustrated.

**Implement sheds**, K. J. T. EKBLAW (*Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul. 1 (1916), pp. 19, figs. 6*).—This paper discusses the design of implement sheds and gives information with illustrations on the open shed, wide inclosed, and two-story types, and space requirements and selection of building material.

**Farm residence heating**, L. W. EGGLESTON (*Trans. Amer. Soc. Agr. Engin., 9 (1915), No. 1, pp. 41-49, figs. 10*).—The general features of steam and hot water heating of farmhouses are described and illustrated.

**Electric lighting systems for farm use**, C. H. ROTH (*Trans. Amer. Soc. Agr. Engin., 9 (1915), No. 1, pp. 34-40*).—The author attempts to classify farm light-

ing systems, his purpose being apparently to advance a step in standardization. The systems are classified as follows: (1) Plants that give light only when the generator and engine are running; (2) plants that give light only from the battery, the generator being used only for charging the battery; (3) plants that give light from the battery or from the battery and generator combined; and (4) plants that give light either from the battery or generator, or from both.

The following general types coming under each class are suggested: Manual—plants that are entirely manually started, operated, regulated, and stopped; semiautomatic—plants that are partially automatic in some one or more features, but not entirely so; all automatic—plants that are entirely automatic in starting, regulating the voltage and charging battery, automatically stopping when the charge is complete or no lights are in use.

With reference to voltage, it is stated that "32 volts has become a standard for small plants having lights in a small area; 115 volts is better if the distribution system covers a considerable distance from the plant and if motors other than small household motors are to be used." With reference to speed of generator, it is stated that "if belt driven, 2,300 revolutions per minute or less gives general satisfaction. If direct connected to the engine the speed should be lower, perhaps 800 to 1,000 maximum, although experiments are continually being made to produce higher speed engines that are not noisy and have a reasonable life."

Sewage disposal for country homes, F. F. FRAZIER (*Kans. Agr. Col. Ext. Bul. 6 (1916), pp. 30, figs. 6*).—This bulletin describes and illustrates the design and construction of small sewage disposal systems consisting of septic tanks and tile absorption areas. The author lays more stress on the chemical and bacteriological phases of sewage purification than has been the custom in previous reports by others on the subject, and his recommendations indicate that some study along that line has been made.

## RURAL ECONOMICS.

[A study in social dynamics], J. M. GILLETTE (*Quart. Pubs. Amer. Statis. Assoc., n. ser., 15 (1916), No. 116, pp. 345-380, figs. 2*).—The author has endeavored to determine statistically the rate of natural increase and the factors accounting for the increase in the rural and urban population of the United States. He describes in detail the method used and the results obtained. The natural increases as determined by his method are shown in the following table:

*Rates of birth, death, and natural increase in the United States for the decade 1900-1910.*

Division.	Birth rate.		Death rate.		Rate of natural increase.	
	Rural.	Urban.	Rural.	Urban.	Rural.	Urban.
New England.....	21.0	24.4	16.0	17.1	5.0	7.3
Middle Atlantic.....	25.5	26.4	14.8	16.8	10.7	9.6
East North Central.....	25.2	24.7	12.8	13.9	12.4	10.8
West North Central.....	28.4	22.5	10.3	12.4	18.1	10.1
South Atlantic.....	34.4	25.4	15.5	19.4	18.9	6.0
East South Central.....	34.4	25.4	14.7	18.0	19.7	7.4
West South Central.....	26.4	27.0	12.5	16.8	23.9	10.2
Mountain.....	31.6	25.5	10.5	15.0	21.1	10.5
Pacific.....	24.6	20.4	12.0	13.8	12.6	6.6
United States.....	30.4	25.2	13.5	16.4	16.9	8.8

His analysis reveals the fact that the increase of 11,826,000 for the urban districts consisted of 924,000 persons added by incorporation, 4,849,000 by immigration, 3,637,000 by rural migration, and 2,426,000 by natural increase. The increase of 4,151,000 in the rural districts was due to additions by migration of 1,290,000 and a natural increase of 2,861,000.

Some economic factors which influence rural education in Wisconsin, E. MERRITT and K. L. HATCH (*Wisconsin Sta. Research Bul. 40 (1916), pp. 51, figs. 20*).—In this study, conducted in cooperation with the U. S. Department of Agriculture, it was found that the number of farms in the northern portion of the State were increasing while in the southern portion there was a decrease in the number, the decrease being due to the elimination of farms containing between 20 and 99 acres. The size of the farm family was decreasing, due to the fact that the rural population contained a smaller percentage of those of foreign birth than formerly.

In the extreme northern and southern parts of the State there were a large number of schools which had an enrollment of 15 pupils or less. Apparently these small schools in the southern part of the State were results of not only a decrease in the number of farms but also in the size of the farm family. In the northern portion of the State the small school was due to the sparse settlement of the rural districts.

An effort was made to ascertain the relationship between tenantry and rural education. It was found that there were two classes of tenants in Wisconsin, those who are related to the owners of the farms and those who are not. The former, as a rule, are a more or less permanent class in a community and therefore have a vital interest in the system of education which is being developed. It was found also that the percentage of the total farmers who were tenants and married a specified number of years decreased as the number of years married increased. In other words, there is a ladder by which the tenant farmer passes from the tenant class into that of the farm owner. Since the tenant, as a rule, has been married a smaller number of years than the owner, he naturally has a smaller number of children and a large proportion of them are not of school age.

In the study of the school attendance it was found that the city children were attending school in relatively greater numbers than rural children between the ages of 6 and 14, while the reverse was true for those between 15 and 20 years of age. The economic conditions under which the country boy and girl live apparently enable them to attend school in larger numbers in the more advanced years, whereas the smaller children in rural districts are unable to attend on account of the distance that many of them live from the schools and the poor condition of many of the country roads.

The system of education carried on by the public schools and the extension department of the agricultural college was found to provide no training for the boy after he left school until he takes up farming on his own account. This period is generally between the ages of 18 and 25. The returns also indicated that the girls were leaving farms faster than the boys, and that the children were leaving the smaller farms faster than those living on the larger ones.

Data as to the value of a high-school education indicated that it was a good investment for the farmer. It also paid the boy who intended ultimately to be a farmer to stick by the farm rather than to engage in another occupation.

Additional information was obtained to ascertain what were the sources of incentive to adopt the more progressive agricultural practices, labor incomes of farmers with different types of education, costs of instruction in different types of agricultural schools, etc.

Twelve ways to meet the new economic conditions here in the South, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 33 (1917), pp. 3-7*).—The author has pointed out how the southern farmer can best succeed under boll-weevil conditions. He advises the growing of food for the family and live stock on the farm, the growing of an early maturing type of cotton, and thorough culture and manuring of the land.

The use of a diary for farm accounts, E. H. THOMSON (*U. S. Dept. Agr., Farmers' Bul. 782 (1917), pp. 18, figs. 5*).—The author believes that the diary may serve two purposes: (1) To keep those records which are of a financial nature, such as receipts and expenditures; and (2) to keep those records of farm work and production, such as dates of planting and harvesting, crop yields, feed fed to live stock, etc. The bulletin describes several different kinds of diaries and shows how various farm accounts may be kept in diary form.

Report of the commission on land colonization and rural credits of the State of California, E. MEAD ET AL. (*Rpt. Com. Land Colon. and Rural Credits Cal., 1916, pp. 87*).—In this report are discussed the history of land settlement, methods of financing settlers in California, and methods used in land settlement in European and other countries.

Report on the working of the cooperative societies in Bengal, 1914-15, J. M. MITRA (*Rpt. Work. Coop. Socs. Bengal, 1914-15, pp. 29+II+XXX+3*).—The author points out the progress which has been made in the work of these societies, and describes the activities of the central banks, the agricultural and nonagricultural societies, and other forms of cooperative agricultural effort, such as grain banks, cooperative dairies, sugar factories, weavers' societies, and supply societies. Statistical data are given showing the membership of the associations and the amount of business done.

Insurance against loss from hail, H. LAGRANGE (*Bul. Dir. Gén. Agr. Com. et Colon, Tunis, 20 (1916), No. 88, pp. 111-144*).—The author discusses briefly the methods of developing hail insurance and the experience with it in France, Algeria, Tunis, Switzerland, Germany, Austria, Bulgaria, Canada, and Italy.

A summary of the market situation in Boston (*City Planning Bd., Boston, Doc. 118 (1915), pp. 175, figs. 19*).—This report sets forth the sources of Boston's supply of perishable food, the organization of the wholesale and retail trade, internal transportation, problems of general transportation, and an outline of a plan for improving the methods of distributing the food supply within the city. There is also included information regarding the receipts of foodstuffs and prices and an extended bibliography on public markets.

[Marketing of live stock], L. D. HALL (*Iowa Yearbook Agr. 16 (1915), pp. 442-445*).—The author describes the activities of the Office of Markets and Rural Organization of the U. S. Department of Agriculture in studying the marketing of live stock.

Principles of the grain trade of western Canada, C. B. PIPER (*Winnipeg, Canada: Author, 1915, pp. VII+179*).—The author has discussed the method of marketing grain in western Canada under the topics of transportation, inspection, country elevators, terminal elevators, grain exchange and the marketing of grain, financing the crop movement, the Canada Grain Act and Board of Grain Commissioners, and the economic relation of the grain trade to the farm.

Wholesale prices, Canada, 1914, R. H. COATS (*Canada Dept. Labor, Wholesale Prices, Canada, 1914, pp. XVII+259, figs. 15*).—This report continues the information previously noted (*E. S. R., 32, p. 490*), adding data for 1914.

Wholesale prices, Canada, 1915, C. W. BOLTON (*Canada Dept. Labor, Wholesale Prices, Canada, 1915, pp. XVI+312, figs. 27*).—This report continues the information noted above, adding data for 1915.

[Agricultural statistics of the United States] (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Statis. Abs. U. S., 38 (1915), pp. 113-154, 506-511, 518-528*).—There are brought together in this statistical abstract data regarding the number of farms, extent of improved and unimproved land, value of agricultural land and buildings, area, production and value of crops, number and value of live stock, total and per capita consumption of important agricultural products, and prices of agricultural products. The data given are for 1915 with comparative figures for earlier years.

English agriculture, B. SKALWEIT (*Ber. Landw. Reichsamte Innern, No. 37 (1915), pp. VII+535, pls. 3*).—In this volume are discussed the climate, topography, agricultural institutions, soil, types of farming, changes in the method of live stock and crop production, home supply of food, and the imports of agricultural products.

A short history of English rural life, M. FORDHAM (*London: George Allen & Unwin, Ltd., 1916, pp. XVI+183, pl. 1*).—The author gives a brief history of English agriculture and references to acts of Parliament and royal ordinances relating to agriculture and agricultural laborers and landlords.

Report of the departmental committee on food production in Ireland (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Dept. Com. on Food Production, 1 (1915), pp. VI+22; 2 (1916), pp. VI+94*).—This report discusses the status of agriculture in Ireland relative to land in crops, number of live stock, prices of agricultural products, and facilities for obtaining agricultural implements and machinery. The second volume contains the minutes of the hearings held in connection with the gathering of evidence for the report.

[Agricultural statistics of Russia] (*Rec. Données Statis. et Écon. Indus. Agr. Russie et Pays Étrangers, 9 (1916), pp. XIV+649*).—This report continues data previously noted (*E. S. R., 33, p. 193*), adding data for 1914-15.

Agricultural statistics of Java and Madura (*Jaarc. Konink. Nederlanden, Koloniën, 1913, pp. 64-76*).—This report continues data already noted (*E. S. R., 32, p. 894*), adding data for 1913.

[Agriculture in Japan] (*Statis. Rpt. Dept. Agr. and Com. Japan, 31 [1914], pp. 1-121*).—These pages continue the data previously noted (*E. S. R., 33, p. 395*), adding information for 1914.

## AGRICULTURAL EDUCATION.

History of the Maine State College and the University of Maine. M. C. FERNALD (*Orono, Me.: Univ. Maine, 1916, pp. 450, pls. 40*).—The author presents in the first eight chapters the important facts and incidents, in chronological order, of the different administrations of the University of Maine. These are followed by chapters, written by different members of the university faculty, relating to special departments and interests of the institution, including, among others, the development and progress of the college of agriculture and the organization and development of the experiment station.

[Proceedings of the agricultural and domestic science sections of the high school conferences for 1912, 1913, 1914], edited by H. A. HOLLISTER (*Univ. Ill. Bul., 10 (1913), No. 19, pp. 50-65, 106-115; 11 (1913), No. 17, pp. 63-85, 130-143; 12 (1915), No. 21, pp. 95-114, 163-172*).—The reports of the proceedings of the agricultural section of the Illinois high school conferences include for 1912 an outline of a one-semester course for high schools in forest, orchard, and garden work, by A. W. Nolan; and abstracts of papers on School and Home Gardens, by C. Colvin; Cereal and Forage Crops, by A. J. Beatty, indicating the extent of instruction in agriculture in Illinois high schools; and on how

much attention is being given to dairy instruction in Illinois high schools, by C. H. Keltner. For 1913, abstracts are given of papers on the Introduction of Agriculture in High Schools, by W. L. Eikenberry; A Course in Animal Husbandry, by R. R. Snapp; Country Life Clubs, by G. W. Brown; and A Course in Soils for Secondary Schools, by J. W. Morgan. For 1914, papers are given on Extension Work for the High School, by L. F. Fulwiler, describing the extension work of the Mt. Pulaski Township High School; Collection and Organization of Suggestions for Teaching High School Agriculture, by I. A. Madden; and the Differentiation of Fundamentals and Accessories in the Content of High School Agriculture, by R. Muckelroy.

The proceedings of the home economics section include for 1912 a report of the executive committee on the revision of the syllabus for the grades and high school, including a summary of the time and place given to domestic science in high school curricula, and a discussion of The Teaching of Millinery in the High School, by Edith Welty. For 1913, suggestions are given by Miss Helena M. Pincomb as the result of a study in values or the evolution of domestic science, and abstracts of papers on The Principles of Natural Science Fundamental to the Teaching of Domestic Science in the High School, by Miss Mary Moore; The Method of Teaching Principles and Experiments, by Miss Thomas; and Art Principles and Suggestions for Their Application, by Miss Mary B. Hill. For 1914, a report is given from the executive committee, including outlines adopted by the section, as to the first four lessons in sewing for the fifth grade and the first four lessons in cooking and housekeeping for the seventh grade, and a paper on The Correlation of Drawing and Design with Domestic Arts in the Home Arts Course at New Trier Township High School, by Miss Olive L. Grover.

Education as it affects agriculture, C. TURNOR (*Jour. Cent. and Assoc. Chambers Agr. and Agr. Rec. [London], n. ser., 5 (1916), No. 42, pp. 93-97*).—This is a report on the question of education in its relation to agriculture with special reference to the problem of how to increase the annual output of skilled cultivators of and workers on the land, presented by the education committee of the Central and Associated Chambers of Agriculture of Great Britain at a meeting held July 11, 1916.

Attention is called to the fact that 50 years ago the number of men working on the land in the United Kingdom was greater by 1,000,000 than it is to-day, and to the concurrent steady decline in the production of the land. The present status of elementary, intermediate, and advanced agricultural education, and the training of teachers, is briefly reviewed. The committee recommends that the instruction of the elementary schools be made more practical and more truly based upon surrounding life; that new schools be established similar to the centralized continuation day schools existing in Canada, as well as a system of lower grade instruction centers with courses that would review, complement, and give a more directly vocational bearing to the practical work already done in the schools for boys and girls, a new type of farm school for boys and girls between 13 and 18 years of age, to continue the instruction from the elementary school and definitely prepare them for settling on the land either in the United Kingdom or in the British Dominions, and farm lads' clubs; that definite measures should be taken to interest the children in town schools in country life and to induce more poor-law children to become interested in the cultivation of the land; that as far as possible all reformatories and industrial schools should have farms attached and the pupils more directly encouraged to study agriculture; that continuation instruction should be made compulsory; and that training should be developed to enable country children to enter the teaching profession.

Fifteenth annual general report of the Department of Agriculture and Technical Instruction for Ireland (*Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 15 (1914-15), pp. V+219*).—This is a report on the department's administration and funds and the details of its work during 1914-15, including agricultural and technical instruction.

Exercises in agriculture, S. H. DADISMAN (*Chicago: Lyons and Carnahan, 1916, pp. 160, figs. 34*).—This laboratory manual and notebook contains 100 exercises which have been tried in high schools by the author and are recommended for laboratory work, two periods each week if possible, in a one-year course in agriculture. They comprise studies of plants, animals including poultry, soil and plant growth, farm mechanics, pomology, potatoes, the hotbed, the garden plat and record, forestry, weeds, birds, collecting and mounting insects, and farm management. A minimum list of apparatus and material for high-school agriculture is included.

One hundred exercises in agriculture, J. H. GEHRS and J. A. JAMES (*New York: The Macmillan Co., 1916, pp. XI+222, figs. 60*).—The exercises outlined in this laboratory manual and notebook deal with soils, field crops, farm animals including poultry, plant propagation, horticulture, and farm management. They are the outgrowth of the author's work in teaching agriculture in the high schools of Missouri and Wisconsin. Lists of helpful government publications and of equipment and supplies are included.

Courses of study in agriculture and minimum of required equipment for the farm-life schools of North Carolina, E. A. HODSON (*Raleigh, N. C.: Dept. Pub. Instr., 1915, pp. 60, figs. 22*).—This bulletin contains an outline of the four-year course in agriculture and related subjects and the minimum of general equipment, with estimated cost, for approved farm-life schools in North Carolina; also suggested additional equipment needed for work in the special departments, suggested text and reference books, and lists of books and bulletins for the library. The agricultural work has been outlined to meet the needs of the boy or girl who does not intend to go beyond the high school. Students who are preparing for college may take the regular high-school course and as much of the agricultural work as possible. The agricultural instruction includes botany and the elements of agriculture in the first year, field crops, vegetable gardening, and fruit culture in the second year, farm animals, feeding live stock, dairying, and poultry raising in the third year, and soils and fertilizers and rural economics in the fourth year. Practical work is outlined for each subject.

[Rural school agriculture] (*Cornell Rural School Leaflet, 10 (1916), No. 1, pp. 426, pls. 2, figs. 238*).—This leaflet is devoted to (1) studies of birds, animals, insects, plants, and trees for 1916-17, as outlined in the New York State Syllabus, including among others the following articles: The Pig, by E. S. Savage; Hog Cholera, by R. R. Birch; The Honey Bee, by Anna B. Comstock; Legumes, by G. F. Warren; The Bean, by Anna R. Comstock; Field Beans, by E. V. Hardenburg; A Serious Bean Disease, by M. F. Barrus; The Collection and Preservation of Specimens of Plants, by K. M. Wiegand; The Soil, by E. O. Fippin; and Ten Lessons on the Apple, by E. L. Overholser; (2) home making, including Directions for Canning and Jelly Making, by Helen Knowlton; and an article on Yeast and Bread Making, by Flora Rose; and (3) suggestions to teachers, and articles on Corn Day; General Exhibitions for Farmers' Week, February, 1917; Exhibitions, Fairs, and Competitions; and The Nature and Procedure of Junior Home Project Work, by F. L. Griffin. A list of reference books pertaining to the subjects treated in the leaflet is appended.

The story of the forest, J. G. DORRANCE (*New York: American Book Co., 1916, pp. 237, figs. 113*).—This book, which has been prepared chiefly for use

in the schools, discusses the forests of America, the tree and how it lives and dies, how to know the trees, work in the woods, by-products of the forest, and trees in American history.

**The principles of feeding farm animals**, S. BULL (*New York: The Macmillan Co., 1916, pp. XIX+397, figs. 87*).—This volume aims to present the scientific facts underlying the art of feeding animals. Somewhat definite rules are given regarding the feeding of different classes of live stock and the formulation of rations. Instead of devoting separate chapters to the feeding of the different classes of farm animals, the use of each of the principal feeds for the different species and classes of live stock is discussed. Particular attention is given to the fertilizing values of feeds and rations. The book is intended for use as a college text in general feeding as well as by the farmer who has not had a technical education in agriculture.

**Judging horses as a subject of instruction in secondary schools**, H. P. BARROWS (*U. S. Dept. Agr. Bul. 487 (1917), pp. 31, figs. 16*).—Specific directions are given for teaching the judging of horses, classroom discussion, practice judging, estimating the age of a horse and matters of unsoundness, comparative judging, and demonstrations.

**Poultry production**, W. A. LIPPINCOTT (*Philadelphia: Lea & Febiger, 1916, 2. ed., rev. and enl., pp. X+17-517, pl. 1, figs. 239*).—This is the second revised and enlarged edition of this text, previously noted (*E. S. R., 32, p. 570*), including the addition of a chapter on Poultry Diseases and Parasites.

**Lessons on poultry for rural schools**, F. E. HEALD (*U. S. Dept. Agr. Bul. 464 (1916), pp. 34, figs. 13*).—Thirteen lessons on poultry raising, arranged in seasonal sequence, are outlined, including class study and correlations, reinforced by practical exercises in or near the school, and the home project. These lessons are preceded by general directions for organizing home or club project work and supplemented by specimen forms for district poultry surveys and a census, a pupil's monthly summary of the laying flock, monthly account, balance sheet, cropping plans, and poultry club report, a list of publications related to the subject, etc.

**Mechanical drawing for the farm and agricultural school**, G. F. KROGH (*Bul. Univ. Minn., Gen. Ser., No. 43 (1916), pp. 72, pls. 8, figs. 84*).—This bulletin covers the general principles of drawing, gives a few simple exercises of geometrical construction, graphic methods to show crop yields, etc., maps and topographical drawings, and various methods of representing engineering and architectural data in the form of drawings, and supplies the standardized symbols used in the various lines of drawing for different representations. It has been prepared for use in agricultural schools and for the farm.

**Agricultural arithmetic**, W. T. STRATTON and B. L. REMICK (*New York: The Macmillan Co., 1916, pp. A+239, figs. 50*).—This text is adapted to the requirements of advanced classes in rural elementary schools, agricultural high schools, and other high schools giving instruction in agriculture. Its purpose is to present the basic principles of arithmetic by making use of problems met in daily experience in rural communities, including farm accounts, graphs and their application, percentage, practical measurements, gain and loss, commission, taxes, insurance, interest, business papers, powers and roots, and ratio and proportion.

**Rural arithmetic**, A. O. THOMAS (*New York: American Book Co., 1916, pp. 288, figs. 93*).—In this book, which may be used as an auxiliary text in either grammar or high schools, the principles of arithmetic are applied to the material with which the farmer comes in daily contact. The problems deal with the parcel post; land measurements; labor, machinery, and crops; feeding; farm animals; farm records and accounts; soils and rainfall; light, fuel, and

water; building; taxation, bank account, insurance, and the market; household economics, etc. Tests for accuracy and speed, 100 proficiency questions, reference tables, and the answers to the problems are included.

**Household arts and school lunches**, ALICE C. BOUGHTON (*New York: Russell Sage Foundation, 1916, pp. 170, pls. 11*).—This report is one of the 25 sections of the report of the Education Survey of Cleveland conducted by the Survey Committee of the Cleveland Foundation in 1915. It deals with (1) household arts in elementary schools, its growth in the United States, and its growth and present status in Cleveland; (2) the relation of household arts to elementary education; (3) infant hygiene; (4) household arts in Cleveland high schools; (5) the relation of household arts to secondary education; (6) elementary school lunch service; and (7) high school lunch service.

### MISCELLANEOUS.

**A brief statutory history of the United States Department of Agriculture**, F. G. CAFFEY (*U. S. Dept. Agr., Off. Solicitor [Pub.], 1916, pp. 26*).—A reprint of the article previously noted (*E. S. R.*, 34, p. 796).

**Federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations** (*U. S. Dept. Agr., States Relations Serv. [Pub.], 1916, pp. 44*).—A revision to August 15, 1916, of the circular previously noted (*E. S. R.*, 35, p. 94).

**Twenty-ninth Annual Report of Vermont Station, 1916** (*Vermont Sta. Bul. 199 (1916), pp. 16*).—This contains the organization list, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1916, and a report of the director on the publications and work of the station.

**Twenty-ninth Annual Report of Vermont Station, 1916** (*Vermont Sta. Rpt. 1916, pp. XX+726, pls. 68, figs. 105*).—In addition to the material noted above as Bulletin 199, this contains reprints of Bulletins 191–193, previously noted, and of Bulletins 194–198, abstracted elsewhere in this issue.

**Concerning certain technical bulletins and concerning the annual report** (*Vermont Sta. Circ. 11 (1916), pp. 4, figs. 8*).—A brief statement regarding the distribution of Bulletins 194–201 and the annual report of the station.

**Index to Popular Bulletins 1 to 100** (*Washington Sta., Index Pop. Buls. 1–100 (1916), pp. 30*).—This is a combined subject and author index.

## NOTES.

---

**Georgia College.**—G. R. Skinner and W. H. Allen have succeeded C. J. Goodell and D. J. Taylor as assistant in animal husbandry and supervisor of poultry clubs, respectively. C. A. Whittle has resigned as editor-librarian, J. M. Purdom, jr., being appointed editor and Miss Nelle M. Reese, librarian. M. C. Gay has been appointed field agent in marketing.

**Missouri University and Station.**—C. E. Mangels, assistant chemist at the Ohio Station, has been appointed instructor in agricultural chemistry and assistant in the station beginning April 1. Mitchell D. Wood has succeeded C. W. Sheppard, who is to take up farming, as assistant in animal husbandry.

**New Jersey College and Stations.**—The short courses in agriculture, which closed February 21, were completed by 98 students, 39 being in general agriculture and dairy farming, 27 in fruit growing and market gardening, 22 in poultry husbandry, and 10 in home economics.

J. W. Day has resigned as assistant in agronomy in the college and Ralph M. Hubbard as field assistant in horticulture in the state station. Miss Carrie E. Pimm has been appointed assistant extension specialist in home economics.

**Porto Rico Federal Station.**—Harvey E. Thomas, assistant plant pathologist of the Virginia Station, has been appointed scientific assistant in plant pathology.

**South Carolina Station.**—The division of entomology is completing plans for a field laboratory in one of the coastal counties, for the study of nematodes and American mole crickets. Experiments have been continued in regard to the making of home boiled concentrated lime-sulphur wash, and a formula has been worked out which gives a very satisfactory wash of the same specific gravity as the commercial preparations.

Twelve additional poultry houses have been constructed to house selected breeding pens of Barred Plymouth Rocks, Single Comb Rhode Island Reds, Orpingtons, and Single Comb Black Minorcas, and the various experimental and breeding pens of heavy-laying Single Comb White Leghorns. Experiments are under way to determine the relative value of anthracite coal and kerosene as fuels for heating brooder stoves in the South. A special brooder house has been built for this experiment.

**Texas College and Station.**—The state legislature has established a West Texas Agricultural and Mechanical College of a grade coordinate with the existing institution, as well as a junior college located elsewhere to give two years of high school agriculture and two years corresponding to the freshman and sophomore years of college work. The location of the West Texas college is to be determined by a board consisting of the governor, lieutenant governor, state commissioner of agriculture, state superintendent of public instruction, and two members of the legislature.

V. L. Cory, superintendent of the Denton substation, resigned December 31, 1916, and was succeeded on January 25 by C. H. McDowell, a 1912 graduate of the college, previously engaged in farming and extension work in the State. H. Lebeson, assistant chemist, resigned February 20 and was succeeded by Charles Buchwald, and he in turn by G. B. L. Smith.

**Vermont University and Station.**—Gardner Smith Fassett, trustee of the institution from 1890 to 1914, died January 19 at the age of 85 years. During his entire period of service he was a member of the station board of control and actively associated with the management of the college farm and the construction of many of the buildings.

**Dominion Experimental Farms.**—The new experimental farm at Morden in South Manitoba is to be devoted to experimental work in horticulture on a larger scale than hitherto at any of the prairie stations. Cultural and variety trials and the selection, testing, and breeding of horticultural plants will be carried on. A tract of about 285 acres of land has been secured. Eight acres were planted in the spring of 1916 to apples, plums, cherry hybrids, and small fruits, and considerable nursery seeding was done. Good growth was attained during the summer, although considerable winterkilling is expected. The commercial possibilities of small-fruit growing will also be tested.

**Philippine College of Agriculture.**—Otto A. Reinking, of the Colorado College and Station, has been appointed instructor in plant pathology, and B. M. Gonzalez instructor in animal husbandry. Dr. Manuel Roxas has succeeded Guy Clinton, resigned, as instructor in chemistry.

**Contributions from the U. S. Department of Agriculture and the Experiment Stations to American Chemical Journals.**—Under the heading of A Census of the Periodical Literature of Chemistry Published in the United States, Marion E. Sparks and W. A. Noyes present in the issue of *Science* for February 16 a compilation as to the number and pages of the original papers in chemistry published in five of the principal chemical journals of this country during 1909–10 and 1914–15. In the former period the total number of papers was 796, aggregating 9,225 pages, and for the latter period, 1,415 papers and 13,624 pages.

It is of interest to note that the publications of the government bureaus, experiment stations, etc., which are grouped together, numbered in 1909–10, 93, aggregating 827 pages, and in 1914–15, 253, aggregating 2,247 pages. The research papers of the general scientific institutions numbered 43, aggregating 443 pages, in 1909–10, and 133, aggregating 1,277 pages, in 1914–15.

**Miscellaneous.**—A committee of representative agricultural leaders has been appointed by the president of the Board of Agriculture and Fisheries of Great Britain, to advise him on questions pertaining to the increased production of food. Hon. R. E. Prothero is chairman of this committee and among others may be noted Sir Sydney Oliver, F. L. C. Floud and T. H. Middleton of the board, A. D. Hall and W. W. Berry of the Development Commission, and Prof. W. Somerville.

The membership of the committee on agriculture of the U. S. National Research Council is announced as follows: Raymond Pearl, chairman, E. W. Allen, C. L. Alsberg, H. P. Armsby, Eugene Davenport, E. M. East, L. O. Howard, L. R. Jones, W. H. Jordan, K. F. Kellerman, J. G. Lipman, Theobald Smith, W. J. Spillman, and W. M. Wheeler.

According to a recent note in *Nature*, an institute for research in genetics was opened in April, 1916, at Potsdam in connection with the Agricultural High School of Berlin. Prof. Erwin Baur is serving as director of the institute.

Dr. Johanna Westerdijk has been appointed associate professor of phytopathology in the University of Utrecht. She is said to be the first woman to receive an appointment of this nature in Holland.

Horace Cardinell, a 1914 graduate of the Oregon College, has been appointed horticulturist for the Brazilian Government, for work in the comparatively undeveloped southern section of the country.

## CONTENTS OF VOL. 36, NO. 7.

---

Editorial notes:	Page.
The experiment stations and the war.....	601
The coordination of science and practice in agriculture.....	604
Recent work in agricultural science.....	609
Notes.....	694

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Preliminary notes on the carbohydrates of the Musci, Mason.....	609
The destruction of pentoses in the course of alcoholic fermentation, Pellet....	609
The mode of action of plant peroxidases, Reed.....	609
The relation between oxidase and catalase in plant tissues, Reed.....	610
Elasticity of coagulum produced in cows' milk by rennet, Allemann and Schmid	610
A contribution to the bacteriology of silage, Sherman.....	611
Minutes of evidence taken on edible and oil-producing nuts and seeds.....	611
Report of Committee on Edible and Oil-Producing Nuts and Seeds.....	611
Watermelon seed from the Sudan.....	611
The essential oil of <i>Cinnamomum oliveri</i> , or Brisbane sassafras, Hargreaves....	611
A method for the estimation of very small amounts of potassium, Hamburger..	611
New method for estimating lime and potash in soils, Keitt and King.....	611
The ammoniacal nitrogen of peats and humus soils, Ellis and Morison.....	612
Dilute acids and the phosphorus compounds of the soil, Russell and Prescott..	612
The nature of the phosphates contained in mineral phosphates, Robertson....	613

	Page.
Loss of phosphoric acid in fusion with ammonium fluorid, Davis and Prescott.	613
Estimation of calcium in ash of forage plants and animal carcasses, Kuzirian.	613
A new limestone tester, Hopkins.	614
The determination of humus by means of a simplified procedure, Jakobsen.	614
The estimation of carbohydrates, V. Davis.	614
New contributions to the analysis of milk, Ackermann.	614
The composition of cottonseed meal and cotton seed, Fraps.	615
Conservation of fruit, fungi, truffles, and vegetables, Forlani.	615

## METEOROLOGY.

Report of the chief of the Weather Bureau, 1916.	615
Report of the meteorological station at Berkeley, California, for 1915, Reed.	616
Rain and snow fall of Canada, 1903-1913, Stupart.	617
Temperature observations during the year 1914, Stephansen.	617
Temperature changes from terrestrial radiation and relation to growth, Roster.	617

## SOILS—FERTILIZERS.

Agricultural geology, Rastall.	617
On taking samples of soil for soil surveys, Russell.	617
[Soil studies], Morse.	617
Soil survey of Yell County, Arkansas, Deeter and Lounsbury.	618
Composition of Hawaiian soil particles, McGeorge.	618
Summary of Illinois soil investigations, Hopkins, Mosier, and Bauer.	618
Tazewell County soils, Hopkins, Mosier, Van Alstine, and Garrett.	619
The principal soil areas of Iowa, Stevenson.	619
Soil survey of Grenada County, Mississippi, Tharp and Hogan.	619
Soil survey of the Bitterroot Valley area, Montana, Eckmann, and Harrington.	620
Geology of Cincinnati and vicinity, Fenneman.	620
Soil survey of Dorchester County, South Carolina, Latimer et al.	620
Soils of Grayson, Lee, McLennan, Titus, and Tyler Counties [Texas], Fraps.	620
Soil survey of Smith County, Texas, Schoenmann et al.	621
Soil survey of Franklin County, Washington, Van Duyne et al.	621
Calcium compounds in soils, Shorey, Fry, and Hazen.	621
Studies on the lime requirements of certain soils, Wild.	622
The phenomenon of absorption in its relation to soils, Prescott.	622
Definition of soil fertility by means of analysis of plants, Savvin (Sawine).	622
Processes in relation to humification of plant residues, Trusov (Troussoff).	622
Soil protozoa and their relation to bacterial flora, I, II, Sherman.	622
The disinfection of soil, Miège.	623
Experiments on the Wisconsin drift soil area, Stevenson and Brown.	623
A modified method of green manuring, Hutchinson.	623
Peat in 1915, Turp.	624
Some sources of potassium, Hirst and Carter.	624
Potash as a by-product from the blast furnace, Wysor.	625
Potash becomes a valuable cement mill by-product, Hewitt.	625
Availability of soil potash, and the preparation of sugar humus, Fraps.	625
Solubility of mineral phosphates, Aita.	626
The utilization of phosphates by agricultural crops, Truog.	626
Report on commercial fertilizers, 1916, Jenkins and Street.	627
Tabulated analyses of commercial fertilizers, Frear et al.	628
Commercial fertilizers in 1915-16, Fraps.	628

## AGRICULTURAL BOTANY.

Plants in health and disease, Weiss, Imms, and Robinson.	628
The raw materials of the plant kingdom, von Wiesner.	628
Physiological characters of plants, II, III, Ivanov.	628
The overlapping of the leaf sheath and its lack of value, Conner and Karper.	628
A contribution to the problem of homotyposis, Harris.	628
Inheritance in crosses between <i>Nicotiana langsdorffii</i> and <i>N. alata</i> , East.	629
Linkage in <i>Primula sinensis</i> , Altenburg.	629
Some correlations in sugar beets, Harris and Hogenson.	629
What is happening to the hawthorns? Standish.	630
Influence of composition and concentration of the nutrient solution, Ayres.	630
Comparison of nutritive solutions in sand and water cultures, Stolgaue.	630

	Page.
Effect of repeated growing of plants in nutritive solutions, Zhemchuzhnikov ..	631
Influence of alkalinity of a solution on the nitrogenous material, Morozov....	631
Significance of potassium ion in synthesis of nitrogen compounds, Stoklasa....	631
Rôle of calcium carbonate in the assimilation of ammonia, Morozov .....	631
Rôle of ammonia in transformation of nitrogenous material, Pränishnikov.....	632
The formation of asparagin by <i>Lupinus luteus</i> , Nikolaeva.....	632
The fixation of free nitrogen by certain fungi, Chambers.....	632
A new case of symbiosis between a bacillus and a plant, Georgevitch.....	632
The assimilation of carbon dioxid, Willstatter and Stoll.....	632
Studies on chemical transformations in leaf of <i>Diospyros kaki</i> , Parrozzani .....	633
On the assimilation of iron by plants, Sidorin.....	633
Changes in potatoes during the resting period, Széll.....	633
Changes in chemical composition of rye under influence of <i>Fusarium</i> , Pomaskii.....	633

## FIELD CROPS.

Yields of spring grains in Illinois, Burlison and Allyn.....	634
Grain drying, Bernstein.....	634
Grading and baling Philippine fibers, Edwards.....	634
One year of the fiber-grading law, Saleeby.....	634
Description of the standard grades of Philippine fibers, Saleeby.....	634
Fiber-grading stations and grading establishments, Saleeby.....	635
Fiber production in the Philippine Islands during 1915, Saleeby.....	635
Important legumes.—I, Peas, vetches, beans, lupine, and lentil, Fruwirth....	635
Why alfalfa sometimes fails in Iowa, Jensen.....	635
Flax culture in South Dakota, Hume, Champlin, and Martin.....	635
Some varieties of Indian gram ( <i>Cicer arietinum</i> ), Howard and Rahman Khan..	635
Cultural experiments of German Potato Culture Station, 1915, von Eckenbrecher.	636
Cuttings for the propagation of potatoes, Kiessling.....	636
Potato variety tests at Kloster Hadmersleben, Heine.....	636
Methods and aims in potato breeding, Holdfleiss.....	636
<i>Solanum commersonii</i> , the swamp potato, Siebert.....	637
Sudan grass, Hutcheson, Hodgson, and Wolfe.....	637
Manurial experiments with sugar cane in the West Indies, Dunlop.....	637
Sugar cane on the experimental fields.—Crops of 1914, Harrison et al.....	637
Sweet clover, Parsons.....	637
Sweet potato culture, Johnson and Rosa, jr.....	638
The proportion of grain to straw in varieties of wheat, Pridham.....	638
Selection plats.—A reminder to wheat growers, Pridham.....	638
[Seed corrosion and its prevention], Molz.....	638
The seed situation in Utah, Stewart.....	638
The seed business in the first year of the war, Heinrich.....	638
Clover and grass seed for spring sowing, 1916, Heinrich.....	638
[Computing actual values of clover and grass seed], Heinrich.....	638
Characteristics of quack grass and western wheat grass, Hume and Sloan.....	638
[The control of hedge mustard with finely powdered kainit], Schnitzler.....	639
Weeds of New South Wales, Maiden.....	639

## HORTICULTURE.

Gardeners' dictionary and instructor, Johnson, edited by Fraser and Hemsley..	639
The complete gardener, Thomas.....	639
Garden planning and planting, edited by Thomas.....	639
Gardening made easy, edited by Cook.....	639
Kitchen and market gardening, Bussard.....	639
[Overhead irrigation results in 1916], Palmer.....	640
Cucumber growing, Halligan.....	640
Commercial onion growing, Sayre.....	640
The use of brine tank refrigerator cars for fruit shipments.....	640
The relation of fruit growing to soil fertility, Thompson.....	640
The Indiana farm orchard operating costs and methods, Woodbury et al.....	640
On the cause of alternate bearing in the apple, Butler.....	640
The identification and classification of pears, Luizet.....	640
Origin and development of hardy, blight-resisting pears, Patten.....	641
The cherry and its industrial culture, Hinzenberg.....	641
Variations of a sexual hybrid of the vine, Baco.....	641

	Page.
Hybrid direct bearers in valley of Rhone in 1916, Desmoulins and Villard . . .	641
Blueberry culture, White . . . . .	641
Fertilizer experiments with cranberries in 1916, Schlatter . . . . .	641
Progress in vegetative propagation of tropical fruits, Wester . . . . .	641
History of the avocado and its varieties, Condit . . . . .	641
The cultivation and fertilization of the avocado in Florida, Krome . . . . .	642
Inherent characteristics of <i>Theobroma cacao</i> , and cacao experiments, Olivieri . .	642
Species and varieties of coffee grown in Java, Wester, trans. by Maury . . . . .	642
The cultivation of guavas in Gujarat, Kulkarni . . . . .	642
Effect of fertilizers on the composition and quality of oranges, Young . . . . .	642
Notes on medicinal plants, Hosking . . . . .	642
Collection, drying, and cultivation of medicinal plants in Russia, Komarov . .	642
Notes on cinchona in Java, Wester . . . . .	643
Bulb growing for amateurs, Thomas . . . . .	643
Gladiolus studies.—I, Botany, history, and evolution, Beal . . . . .	643
Gladiolus studies.—II, Culture and hybridization, Hottes . . . . .	643
Field notes on sweet peas, edited by Morse . . . . .	643
Everybody's flower garden, Thomas . . . . .	643
Studies in gardening, Clutton-Brock . . . . .	644
Garden ornaments, Northend . . . . .	644

## FORESTRY.

Studies of the lumber industry, I, Greeley . . . . .	644
The essentials of American timber law, Kinney . . . . .	644
Instructions for the scaling and measurement of National Forest timber . . . . .	644
Historical review of Canada's timber industry, Lawler . . . . .	644
The forest trees of Canada, Lewis . . . . .	644
Commercial woods of the Philippines: Their preparation and uses, Schneider . .	644
The trees of North Carolina, Coker and Totten . . . . .	645
Western yellow pine in Oregon, Munger . . . . .	645
Hybrids and other new chestnuts for blight districts, Van Fleet . . . . .	645
Fourth biennial report of the state forester, Van Hook . . . . .	645
Report of the state forester for the period ended November 30, 1914, Ferris . .	645
Annual reports Washington state forester for 1915 and 1916, Ferris and Pape . .	645
Report state forest administration in South Australia for 1915-16, Gill . . . . .	645

## DISEASES OF PLANTS.

Prophylaxis in vegetable pathology, Comes . . . . .	645
Diseases of cultivated plants, Delacroix and Maublanc . . . . .	645
Report of the botanist and plant pathologist, Barre . . . . .	646
Report of the mycological department in Tula for 1913-14, Trusova . . . . .	646
Fungus parasites in Province Voronezh in 1912, Bondartsev and Lebedeva . . .	646
Fungus diseases of cultivated plants in Turkestan, Zaprometov . . . . .	647
A monograph of the Uredineæ, Sydow . . . . .	647
The wintering of <i>Colcosporium solidaginis</i> , Mains . . . . .	647
The mosaic disease of tomatoes and petunias, Allard . . . . .	647
A bacterial disease of western wheat grass ( <i>Agropyron smithii</i> ), O'Gara . . . .	647
Notes on an artificial culture of <i>Rhizoctonia crocorum</i> , Diehl . . . . .	647
Sclerotinia blight, a serious disease of snap beans, McClintock . . . . .	647
Physiology of <i>Bacterium malvacearum</i> , Faulwetter . . . . .	648
A rot of endive, Ritzema Bos . . . . .	648
Studies upon the blackleg disease of the potato, Morse . . . . .	648
Potato wilt and tuber rot caused by <i>Fusarium eumartii</i> , Haskell . . . . .	648
History and cause of the rind disease of sugar cane, Johnston . . . . .	648
Resistance in fruits, Riäboi . . . . .	649
The root rot disease of the apple in Virginia, Fromme and Thomas . . . . .	649
Temperature relations of apple rot fungi, Brooks and Cooley . . . . .	649
Phytophthora rot of pear, Schoevers . . . . .	649
Peach scab in Netherlands, Schoevers . . . . .	649
A root disease of prunes, Willis . . . . .	649
[Reports on grape downy mildew] . . . . .	650
The development and the treatment of downy mildew in 1915, Capus . . . . .	650
Diseases of grapevines in Vardar, Viala . . . . .	651
Grape diseases in Greece, Viala . . . . .	651
Observations on the distribution of citrus canker, Mackie . . . . .	651

	Page.
Spore variation in <i>Neopeckia coulteri</i> , Boyce.....	651
Note on occurrence of <i>Peridermium balsameum</i> in Washington, Schmitz.....	651
Inoculation of <i>Abies lasiocarpa</i> with <i>Pucciniastrum pustulatum</i> , Weir and Hubert.....	651
Successful inoculations of <i>Larix occidentalis</i> and <i>L. europæa</i> , Weir and Hubert..	651
Work on the white pine blister rust in Minnesota, 1916, Washburn.....	652
White pine blister rust. Does the fungus winter on the currant? McCubbin..	652
<i>Keithia thujina</i> , cause of serious leaf disease of western red cedar, Weir.....	652
Note on "spike" disease in sandal, Lushington.....	652
A possible cause of "spike" in sandal, Whitehead.....	652
The occurrence of bamboo smut in America, Patterson and Charles.....	653

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Annual report of the governor of Alaska on the Alaska game law, 1916, Strong..	653
The domestic cat, Forbush.....	653
Rats and rat riddance, Forbush.....	653
<i>Bacterium tularense</i> .....	653
Land birds of northern New York, Sawyer.....	653
The food of West Virginia birds, Brooks.....	653
The birds of the Isle of Pines, Todd.....	653
Common insects and plant diseases of farm, garden, and orchard, Rumsey...	653
One hundred notes on Indian insects, Fletcher.....	653
[Insects and control measures in South Africa].....	653
Notes on insects damaging sugar cane in Queensland, Jarvis.....	654
Revision of the Japanese termites, Hozawa.....	654
Transmission of infantile leishmaniasis by fleas, da Silva.....	654
Native food plants and feeding habits of the cotton stainer in St. Vincent....	654
Additional notes on native food plants and feeding habits of cotton stainer....	654
Key to nearctic species of <i>Paracalocoris</i> (Heteroptera; Miridæ), McAtce.....	654
The leafhoppers or Jassoidea of Tennessee, DeLong.....	654
Observations on the ecology of Coccidæ, Teodoro.....	655
Control of <i>Chrysomphalus dictyospermi</i> , del Guercio and Malenotti.....	655
Statistics on the production of silk in France and elsewhere.....	655
The white-marked tussock moth, Webster.....	655
The potato tuber moth, Graf.....	655
The rhododendron tingid ( <i>Stephanitis rhododendri</i> ) in Surrey, Green.....	656
Observations of the biology of <i>Recurvaria nanella</i> , Mignone.....	656
Evolution of the color pattern in <i>Lithocolletis</i> , Braun.....	656
Neuropteroid insects of the Philippine Islands, Banks.....	656
The control of the house fly, Blanchard.....	656
Prevention of fly breeding in horse manure, Copeman.....	656
Some experiments on house fly in relation to farm manure heap, Eltringham..	656
Note on helminthic diseases with special reference to house fly, Shircore.....	657
Filariasis.—Report of two cases in the District of Columbia, Lyon, jr.....	657
A new enemy of maguey, Gandara.....	657
The cabbage root maggot and its control in Canada, Gibson and Treherne.....	657
Breeding the mangold fly and dock fly, Cameron.....	658

# EXPERIMENT STATION RECORD.

VOL. 36.

MAY, 1917.

No. 7.

---

At this time, when the air is surcharged with plans for preparation for war, agriculture occupies an unwonted prominence. The importance of making adequate provision to encourage and assure a high scale of production of the necessities of life ranks in the mind of the public alongside of preparation for the actual military operations. Its realization is more keen and intelligent than ever before, growing out of both the experience of Europe and the special part this country is expected to play at the present time.

Very naturally every agency, and especially every institution, has given consideration to the manner in which it can best contribute to the common end at this time. The agricultural institutions have been quick to realize their place and responsibilities and to see the strategic opportunities of the industry they represent. In many of the States they have furnished the initiative and taken the leadership in measures for insuring adequate supplies through agriculture. They have shown how many-sided the problems in this field often are. These problems touch the whole life and organization of the people—economic, social, and even personal. They develop in a remarkably striking way the interrelations of farming and other lines of business—of providing the supplies for the farmer, as well as those resulting from his labor, when and where they are needed, and hence of uniting and correlating the whole fabric of production, trade, and distribution.

The manner in which the agricultural institutions of the country, especially the agricultural colleges, have thrown themselves into this effort, with promptness, resourcefulness, and broad intelligent understanding, shows the element of strength which they supply and the powerful national resource they are. It makes possible, under efficient organization and cooperation, a mobilization of agricultural resources the like of which has not been seen in this country; and it brings out in strong light the advantage of the policy the Government has pursued in promoting agricultural education and research on a national scale and an intimate type of instruction reaching out to the individual farmer on his land.

The spirit of service so dominant throughout the country has found a quick response in the agricultural experiment stations.

The main question is as to just the part they should play. Some workers are feeling that the opportunity there is less than in certain other avenues—that the occasion calls for putting present knowledge into effective use rather than for further accumulation. According to this view, the chief burden will rest most heavily on the extension service and the other agencies for promoting intimately the business of producing food and clothing. But even if this be true, the experiment stations have their part to perform, and it is by no means a small or insignificant one.

The experiment station is a practical institution in its final reach and purpose; it pursues science for the benefit of agriculture, which is a practical art. It is a source of new information, of advanced knowledge, of expert advice and suggestion; it should be the chief original source of such information in its locality. This makes it resourceful in suggestion and extremely helpful in a time when special emphasis is laid on the endeavor to make every effort count in greater food production and the avoidance of loss and waste. Its corps of experts should be found useful in organizing and planning the agricultural campaign, as well as making it efficient through indirect efforts.

As organizations, the experiment stations should in effect place themselves at the disposal of the country to do the special work which they are organized for, adapting themselves in considerable measure to the present need. This can be done without seriously interfering with established lines of investigation which would suffer if neglected, or very radically changing the general program of activity. Every station has a considerable amount of miscellaneous work and routine activity, flexible in quantity and variable in character. Every station also performs a considerable amount of experimental work and testing designed to give results of quite immediate practical application, and especially adapted to changed economic or local conditions. At a time like this such efforts may be regulated and directed, and if need be enlarged, so as to aid in an important way in increasing the outcome of agriculture, avoiding loss, and utilizing unusual resources, as has the work of the stations in European countries.

Manifestly the first requirement is to recognize the position and the opportunity of the stations at this time, and to a considerable extent this has already been done. They need also to adapt their attitude toward the work in hand, so that they will think and observe outside of the special field they have blocked out and have been following in the past, and will not shrink from interruption if need be. In other words, if they are to realize the full measure of their opportunity they can not remain too exclusively absorbed in their routine investigations or the formulated plan for experiment. As leaders of agricultural thought, they need to be ready to see the field and take the

initiative in doing their special part. This will require that they be watchful, alert, and ready.

The effort in the direction of agricultural preparedness has taken the form of increased production of staple crops, live stock, and other food products by farmers, and utilizing land and labor not employed in agricultural production in ordinary times. While this involves especially the services of the county agent and other agencies for direct stimulation and instruction, it also involves supplying these agencies with reliable information and advice which will make the effort productive. Every experiment station will naturally take an especially active practical interest in the movement for more extensive and greater efficiency in production. It will maintain a close contact with these movements through the county agents and other agencies which are in position to know of the farmers' difficulties and to anticipate their needs.

Unusual vigilance might well be exercised to see that proper tillage is given, that the heaviest yielding or best adapted varieties are employed, and that improved methods are followed so far as these are known. In some cases investigations can be "speeded up" or at least brought to a point where their conclusions and important teachings can be made use of, leaving the more elaborate details to be completed later. The unpublished information of the stations should be brought together and digested, with a view to getting out any facts likely to have special practical importance. High prices will stimulate the farmers to greater effort toward enlarged production and will frequently warrant the employment of practices which are not now general. Unusual conditions and exigencies will justify unusual methods.

The stations can fill a useful place by putting themselves keenly on the alert, bringing their knowledge and their vision to bear in a broad way on the agriculture as carried out in their region, in order to instruct properly the county agents and other advisers of the men in the field. It will be especially desirable to maintain through them a close contact with agricultural practice, and above all to be found ready for cooperation with other agencies in lines which are within their field.

It will be well to keep an unusually sharp lookout for both old and new or unidentified crop enemies or other difficulties. And in this direction the stations can exercise their vigilance and place themselves in position to lend aid and advice promptly. The large losses which are to considerable extent preventable need to be avoided or reduced to the minimum this year. The large amount of study in this country which has made possible more effective control and precautionary measures should now be made available and put into wide operation. Special effort will often be needed to accomplish this,

which can be stimulated and aided by the stations, and they can see to it that failure is not due to lack of placing the knowledge and the means properly before the extension and other publicity agencies. The very fact of unusual efforts at extending agricultural production, often with a diminished or less expert labor supply, will make it increasingly necessary that aid be given in overcoming obstacles which may appear and in seconding the efforts of the extension forces by the best advice and expert assistance that is to be had. Quite frequently, no doubt, the assistance rendered will be in the nature of an experimental demonstration, and its results may be found of intrinsic value as an additional test of the actual efficiency of protective measures.

To some extent also investigation can doubtless be shaped to meet special immediate needs. It will be necessary to conserve supplies of fertility and feed as well as of human foods. Some studies may be needed of waste and bad practice, as a foundation for advice for correcting it.

In some cases the stations may render a special service by averting disaster from well-meaning but poorly advised attempts which may be made by others to aid the farmers. When so many agencies are offering advice and suggestions, there is an element of danger unless some means of discrimination is at hand which will insure the farmers protection from some of their would-be friends. The present is above all a period for safe and sane advice resting on demonstrated knowledge. It is no time to experiment with the farmer or to encourage him to experiment in methods or enterprises of uncertain outcome. To supply the basis for this sound advice and procedure is the function of the experiment stations primarily, working through the extension divisions, the county agents, and similar agencies.

In general, the activities of the stations may be to a considerable extent directed to taking hold of those things which tend to increase production, conservation, and the maintenance of the resources on which production rests. This does not necessarily mean that established lines and projects are to be abandoned or left to take care of themselves, but that these may be adjusted as far as possible to other work which is in the nature of exigency. And, above all, the stations should be ready to adapt themselves to the special needs of the hour and fully alive to their opportunity as well as to the general necessity.

The war has already directed attention as never before to the intimate relations between science and industry, including agriculture, as well as to the vital necessity of fostering these relationships. In England especially, agitation along these lines has been strong and continuous. Nearly two years ago Sir William Ramsay, in an address before the British Science Guild on the national organization of

science, pointed out the need of a vigorous support of scientific research as a war measure. In this he embodied a warning by Dr. Lyon Playfair, sixty-three years previously, in which the latter deplored the holding "to mere experience as the sheet anchor of the country, forgetful that the molds in which it was cast are of antique shape, and ignorant that new currents have swept away the sand which formerly held it fast, so that we are in imminent risk of being drifted ashore."

The publication by the Board of Agriculture and Fisheries of a comparative study of British and German agriculture served to call sharp attention to the lower food producing power of British agriculture and the far smaller efforts given to promoting agricultural instruction and experimentation. In this paper it was shown that although the soil and climate of Germany are the less favorable to agriculture, one hundred acres of land in that country feeds from seventy to seventy-five persons as compared with only forty-five to fifty persons in Great Britain. This advantage of Germany has come about within the last forty years. Various causes are assigned for the change, but a great deal is attributed to the system of agricultural education and research. Thus, the use of artificial fertilizers has largely increased, and according to the article, "the chief factor in developing the use of artificial manures in Germany was unquestionably a well-organized system of technical education. Investigation at the research stations established the precise uses of these manures; trustworthy advice was supplied by institutions, by peripatetic instructors, by technical leaflets, and by agricultural newspapers; and the farmer, even the backward Bauer, like other Germans, brought his methods into line with 'Authority.'" Similar testimony has recently been given by Professor von Rümker of the Royal Agricultural High School of Berlin, who states that "the great progress that agriculture has achieved in Germany during the last quarter of a century is the result of the union of practice with science."

Early in the present year an important letter from Lord Blyth appeared in the *Times*, emphasizing the necessity for the close co-ordination of science with practice in agriculture for the purpose of increasing food production of the country. He proposed the immediate appointment of a commission of men of science to devote its entire attention to research and experimentation. *Nature* reported on January 25 that the formation of such a commission was under consideration and expressed its approval of the undertaking. "Throughout the war," it went on to say, "the agricultural colleges and experiment stations have rendered useful service and have demonstrated more convincingly than ever the close connection between science and agriculture. Indeed, never before has agricultural science had so much recognition as now, either from farmers or from

men engaged in pure science, and it is hoped that the new conditions will do much to strengthen still further the development of scientific agriculture in this country."

The movement toward the fostering of industrial research seems to be extending to all parts of the British Empire. The Canadian Government has appointed an honorary advisory council on scientific and industrial research to advise a cabinet committee (including the minister of agriculture) on all matters relating to the extension and coordination of scientific and industrial research. Considerable special development along experimental and demonstration lines in agriculture is also reported from the Dominion. An experimental flax mill has been erected at the Central Experimental Farms, where experimental work is to be begun with a view to developing the industry, and research laboratories are being established in Manitoba and Saskatchewan for emergency studies of grain rust.

Ontario, where marked efforts are being made to increase land settlement, an agricultural training depot is being organized at one of

In Northern Ontario, where marked efforts are being made to increase land settlement, an agricultural training depot is being organized at one of the experimental farms for the instruction of returning soldiers, as well as several demonstration farms, a plant breeding station, and an agricultural high school. One interesting phase is the utilization of the labor of interned aliens in this section and also in Quebec for the clearing of timberland for eventual use as an experimental substation.

The South Australian branch of the British Science Guild has drawn up plans for a federal institute for original research, designed to give special attention to agriculture and to undertake "research work beyond experimental farming." The guild has realized the importance of studying from a research point of view everything underlying the successful use of the land, including the wellbeing in every respect of the people engaged in farming operations. Its ideas were presented to the Australian premiers, and it is understood that energetic steps are being taken to put some such a plan into effect. Problems relating to engineering, chemistry, coal mining, diseases of cattle, agriculture, bread making, and other matters are on the list in the federal research scheme being worked out by the executive committee of the Advisory Council of Science and Industry for the Commonwealth of Australia.

The French Academy of Science has proposed and recommended the establishment of national laboratories of scientific research, and a commission of the academy has dealt with the matter of institutions for research in agriculture. In a report presented to the academy toward the close of the last year, the important position of agriculture

is described, as well as the great desirability of increasing the farm production per hectare. The commission asserts that the entire system for agricultural encouragement, instruction, and research in France must be reconstructed "from the base to the summit," declaring that "it has been definitely shown that the countries which have made the greatest progress and which obtain from their soil the highest returns, are those which have increased the institutions of research and instruction of the highest rank, and have prepared their rural population to appreciate them, to accept them, and to have full confidence in science. The report asserts further that "all the great progress realized in the domain of agriculture has had its point of departure in the works and discoveries of science."

The commission describes in considerable detail the experiment station system of the United States, which it commends highly. This system is contrasted with the stations and laboratories in France, for which the government in 1913 voted 339,700 francs (about \$68,000), with very small additional revenues from local and similar sources. This sum is shown to be quite inadequate, and to result in limiting the field work and expensive investigations and in restricting considerably the routine functions.

At present the French station is usually devoted to a single branch of industry. The commission argues for fewer stations located in typical agricultural areas and well organized to cover the various phases of the industries, with specialists in each. It is also suggested that the stations should seek the collaboration of farmers, much as have the Danes in their experimental work.

What the commission regards as very serious obstacles are the comparative isolation of the stations from one another and their lack of central supervision. It advocates the appointment of a permanent superior council to guide and direct the work of the stations, assure the proper use of the funds at their disposal, provide for meetings of their personnel from time to time, publish results of their work and abstracts of material of interest appearing elsewhere, and otherwise correlate and unite the scattered institutions into a national system. The establishment of a well equipped central station charged with work of a strictly scientific nature of interest to the whole country, or of such scope and importance that it could not be carried on to the best advantage at the regional stations, is also favored.

The entrance of the United States into the war is of course too recent for extensive developments, but attention may be drawn to the appointment of an agriculture committee of the National Research Council and the active participation of agricultural leaders in the many conferences and campaigns which are the order of the day.

Special mention should be made of the St. Louis conference of April 9 and 10, called by the Secretary of Agriculture and participated in by representatives of the Department and sixty-five officials from the agricultural colleges of thirty-two States and twenty State departments of agriculture. Among the many recommendations of this conference was one for the appointment of two national bodies, one relatively small and to be composed of men of wide knowledge of agricultural matters and executive experience for quite constant service in Washington, and the other a large national advisory body of representatives of the leading agricultural agencies and related interests.

The Federal Government has already organized an interdepartmental committee to formulate a program for food production and conservation, and has a number of plans under consideration. Among these is the material expansion of the work of the Department of Agriculture, enlarging its forces for cooperative demonstration work, home economics, the combating of destructive pests, the utilization of methods for the preservation of perishable products, the safeguarding of seed supplies for 1918, the market news service, assisting with the labor problem, and otherwise to stimulate production, improve distribution, and promote conservation of the food supply. The appointment of a small body of agricultural leaders to give advice as regards national problems, and the creation in each State of a small central division of food production and conservation composed of representatives of the various agricultural and related interests, as well as the formation of county, township, or urban bodies of similar constitution to work in close cooperation with the State central agency, are also suggested. It is estimated that approximately \$25,000,000 will be required to carry these plans into operation.

In this brief review no attempt has been made to present a complete summary of the existing situation. The aim has been rather to cite some suggestive illustrations of the importance being attached in this great world-crisis to the close coordination of the science and practice of agriculture. It is scarcely necessary to point out that this means for all agricultural research institutions an unusual opportunity for service and a corresponding responsibility.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Preliminary notes on the carbohydrates of the Musci, T. G. MASON (*Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1916), No. 2, pp. 13-28, fig. 1*).—In the examination of *Polytrichum commune*, *Thuidium tamariscinum*, and *Sphagnum cymbifolium*, the author found dextrose, levulose, and sucrose present, while maltose was found to be dependent on the presence of starch. Invertase was found to be widely distributed, while diastase and maltase were found in *P. commune* alone. The detection of diastase and maltase was dependent on the presence of appreciable quantities of starch. In *P. commune* and *S. cymbifolium* the hexoses appear to be the chief form in which the carbohydrates descend the stem. In regard to the necessity of a high concentration of hexoses for the synthesis of sucrose by the invertase, it is indicated that "though the experiments quoted in this work exclude the possibility of a high concentration for the whole leaf, yet they do not demonstrate the absence of a localized high concentration."

It is concluded that "the factors that operate in bringing about the synthesis of sucrose in the plant cell are still very obscure" and that it is improbable that invertase in aqueous solution possesses this property.

The destruction of pentoses in the course of alcoholic fermentation, H. PELLETT (*Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 11, pp. 274-276*).—In a study of the composition of molasses the author found, contrary to the general assumption, that arabinose and xylose were decomposed by yeast when present in a mixture of fermentable sugars, the quantity destroyed depending upon the amount of yeast, the temperature, and the length of fermentation.

For destroying the easily fermentable sugars so that the pentoses may be determined by copper with reduction, 50 gm. of ordinary pressed yeast in a solution containing 100 gm. molasses should be used. The fermentation is usually complete in 24 hours without any decomposition of pentoses.

Applying the method to molasses the author found the material to contain no appreciable quantities of pentoses but a nonfermentable substance which is indicated as probably being the material "glutose," described by earlier investigators.

The mode of action of plant peroxidases, G. B. REED (*Bot. Gaz., 62 (1916), No. 3, pp. 233-238, figs. 2*).—Experiments similar to those reported in a study of the platinum reaction previously noted (*E. S. R., 35, p. 713*) have been repeated, using horse-radish root extract and potato peroxidase.

The experiments have shown that just as the platinum is recharged with oxygen by hydrogen peroxid as soon as some of the oxygen has been removed from the platinum by a reducing agent, so the horse-radish and potato peroxidase is recharged by hydrogen peroxid under similar conditions. It is concluded that "in oxidation processes catalyzed by peroxidases two reactions are involved. The peroxidase combines with oxygen from the oxygenases (or from hydrogen peroxid, or possibly from some other source, since it is capable of tak-

ing it from potassium permanganate) to form an intermediate compound which is a more energetic oxidizing agent than the original source of the oxygen. The final stage in the oxidation is then effected by this intermediate compound."

The relation between oxidase and catalase in plant tissues, G. B. REED (*Bot. Gaz.*, 62 (1916), No. 5, pp. 409-412. fig. 1).—The juice of the pineapple in three stages of ripeness (quite ripe and soft, yellow but not soft, and still partly green) was examined for catalase, and the enzyme found to be present in the ripe fruits, with the greatest amount in the juice of the overripe but not in the green fruit. The juices from all of the fruits, however, showed approximately the same peroxidase activity. From the study with platinum black noted above and from the fact that in certain stages of their development pineapples contain oxidases but no catalases, the author concludes that "the substances which effect the decomposition of hydrogen peroxid are not of necessity concerned with the enzymes which accelerate peroxid oxidations. It may be added that the fact that catalase is not universally present in living cells, as Loew [*E. S. R.*, 13, p. 115] and others suppose, has considerable theoretical interest."

The elasticity of the coagulum produced in cows' milk by rennet, O. ALLEMANN and H. SCHMID (*Landw. Jahrb. Schweiz*, 30 (1916), No. 3, pp. 357-383, figs. 2).—A simple apparatus for determining the elasticity of milk curd, which depends on measuring the resistance offered to the withdrawal from the coagulated material of a device of three concentric rings attached to a vertical axis, is described in detail.

Because of the great importance of the elasticity of the curd in the manufacture of cheese, the authors studied, with the aid of this apparatus, the effect of various factors on this property in the coagulation of milk. The results showed that from the beginning of the coagulation the elasticity of the curd increased in direct proportion with the time. Variations in the amount of rennet used, other conditions being the same, produced a direct increase in the elasticity, depending on the amount used. For example, using double the quantity of rennet in a given volume of milk the elasticity of the curd was doubled. The elasticity of the curd also varied directly with the increase of the acidity of the milk, and likewise with the addition of calcium chlorid. The addition of ammonia, however, did not have the exact reverse effect from that of the acid, but, apart from decreasing the acidity, it appeared to exert a detrimental effect on the enzyme.

An increase in temperature to a maximum of 41° C. increased coagulation time. The elasticity of the curd was also directly proportional to the temperature increase, with no apparent maximum. Agitation of the material retarded the coagulation time on an average of about 8 per cent. Previous cooling caused some delay in the time of coagulation, and also a diminished elasticity of the coagulum.

The greatest factor influencing coagulation by rennet was found to be the individuality of the milk. Great variations were observed, not only in the coagulation time but also in the nature of the curd formed. The period of lactation affected the coagulation time in that shortly after calving the time increased, rapidly sinking, however, to a minimum, then again increasing in a few days and remaining fairly constant. No apparent difference was observed either in the coagulation time or nature of the curd produced by the morning or evening milk of individual animals, nor did the feeding of various rations produce any perceptible change. The milk from cows in œstrus coagulated much slower and produced a curd of reduced elasticity. Similar variations were occasionally observed in the milk of animals which had been subjected to sudden climatic changes.

A contribution to the bacteriology of silage, J. M. SHERMAN (*Jour. Bact.*, 1 (1916), No. 4, pp. 445-452).—The author, at the Pennsylvania Experiment Station, has observed the presence of large numbers (over a billion per cubic centimeter of juice) of organisms which, though closely related to the *Bacillus bulgaricus* group of milk and the *B. acidophilus* group of the intestines, appear to differ somewhat from the typical members of these groups, notably by the abundant growth on ordinary laboratory media. It is indicated that silage made from corn is always amply seeded with these organisms, since the aciduric bacilli of silage are constantly found in large numbers on corn fodder.

See also a previous note by Hunter and Bushnell (*E. S. R.*, 35, p. 9).

Minutes of evidence taken before the Committee on Edible and Oil-Producing Nuts and Seeds (*London: Colonial Office, 1916, pp. 233*).—A detailed account of the evidence presented to the departmental committee appointed by the Secretary of State for the Colonies to investigate the edible and oil-producing nut and seed industry in West Africa and to make recommendations for the promotion of industries dependent thereon.

Report of Committee on Edible and Oil-Producing Nuts and Seeds; with a despatch from the Secretary of State for the Colonies (*London: Colonial Office, 1916, pp. 47*).—This reports the findings of the committee from the minutes of evidence as noted above.

Watermelon seeds from the Sudan (*Bul. Imp. Inst. [So. Kensington], 14 (1916), No. 2, pp. 160-162*).—A sample of watermelon seeds (*Citrullus vulgaris*) was found to contain 7.4 per cent moisture and 23.6 per cent of a brownish-yellow oil. The oil yielded the following constants: Specific gravity at 15° C., 0.923; solidifying point of fatty acids, 30.5°; acid value, 8.4; saponification value, 191.4; iodine value, 117.1; Hehner value, 95.1.

The press cake was found to have the following percentage composition: Moisture, 9.5; protein, 18.3; fat, 0.5; starch (by difference), 26.9; fiber, 41.9; ash, 2.9. From these figures the percentage composition of the original seed was calculated and found to be moisture, 7.4; protein, 14; fat, 23.6; starch, 20.6; fiber, 32.2; and ash, 2.2.

The value of the oil and the economic importance of its source is indicated. The press cake is regarded as of little value because of its high fiber content.

The essential oil of *Cinnamomum oliveri* or Brisbane sassafras, G. W. HARGREAVES (*Jour. Chem. Soc. [London], 109 (1916), No. 646, pp. 751-754*).—The oil distilled with steam from the bark and fractionally redistilled under diminished pressure was found to contain approximately the following percentage constituents: Pinene, from 12 to 15; *d*-camphor, from 18 to 20; safrole, from 25 to 27; and eugenyl methyl ether, from 45 to 45. The percentage composition of the oil of the leaves was found to be pinene and phellandrene (?), 25; *d*-camphor, 60; and phenols and other substances, 15.

The analytical data are described in detail.

A method for the estimation of very small amounts of potassium, H. J. HAMBURGER (*Biochem. Ztschr.*, 74 (1916), pp. 414, 415; *abs. in Jour. Chem. Soc. [London], 110 (1916), No. 646, II, p. 448*).—The author calls attention to an error in the capillary tubes used and described in the method for the determination of potassium previously noted (*E. S. R.*, 34, p. 503). With a correctly graduated tube each division equals 0.0004 cc. and corresponds to 0.000074059 gm. of potassium.

A new, rapid, and accurate method for estimating lime and potash in soils, T. E. KEITT and C. J. KING (*South Carolina Sta. Bul. 188, pp. 3-5*).—The method described is as follows:

An aliquot of the soil solution corresponding to 2 gm. of soil is evaporated in a platinum dish on a water bath after the addition of 5 cc. of sulphuric acid

(1:1). The evaporation is completed on a sand bath and the residue ignited at blast-lamp temperature to convert the iron and aluminum salts present into the insoluble oxids. The residue is treated with 25 cc. hot water, washed by decantation, and finally on the filter until free from sulphates. The filtrate is then evaporated to about 50 cc. volume and, after making the solution alkaline with ammonium hydroxid, the calcium is precipitated in the boiling solution by a saturated solution of ammonium oxalate. After allowing to stand for at least three hours the solution is filtered and reprecipitated according to the official method for determining calcium in soils. The filtrate and washings from the calcium determination are evaporated to dryness, the ammonium salts removed, and the potash determined according to the official Lindo-Gladding procedure (E. S. R., 20, p. 512).

Comparative analytical data submitted indicate the accuracy of the procedure.

Advantages claimed for the new method are a considerable saving of time, the rapid removal of soluble salts from the iron and aluminum precipitate by hot water, and the regulation of the amount of reagents used, thus avoiding their removal later in the procedure.

The ammoniacal nitrogen of peats and humus soils, J. C. B. ELLIS and C. G. T. MORISON (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 1-6).—The authors have found that distillation with magnesium oxid by a slightly modified procedure, described in detail, yields fairly constant results for ammonia with the same sample of peat. This amount is many times greater than that yielded in the case of arable soils. Much of the ammonia can be removed by water alone, but no constant ratio has been found between this amount and that obtained by direct distillation. These respective amounts may vary considerably with the depth from which the sample is obtained.

The nature and source of this ammoniacal nitrogen and the conditions of its solubility in the soil water are being studied.

The reaction between dilute acids and the phosphorus compounds of the soil, E. J. RUSSELL and J. A. PRESCOTT (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 65-110, figs. 20).—The extraction of phosphorus from soils by acids and the adsorption of  $P_2O_5$  in the presence of acid are discussed in some detail. Experimental data obtained by the extraction of soils with dilute nitric, hydrochloric, sulphuric, and citric acids are submitted in graphical form. The effect of the time of extraction, strength of acid, and temperature were also studied.

When a soil is shaken with a dilute acid in the process of analysis "the acid dissolves out such phosphorus compounds as it can, and different acids have much the same effect at equivalent concentrations; nitric, hydrochloric, and citric acids give the same results; sulphuric acid, however, gives a somewhat higher result. A reverse reaction at once sets in, however. Some of the  $P_2O_5$  is withdrawn from the solution in spite of the presence of excess of acid. The process is an ordinary adsorption and obeys the usual law. . . . Its extent varies with the different acids; it is much more marked in the presence of nitric than of citric acid." The amount of phosphorus actually determined in a soil extract is, then, not the true amount dissolved but the difference between the two wholly distinct actions.

This reverse reaction explains why the "available  $P_2O_5$ " determined by extraction with dilute acids shows such variations in different methods of analysis and so little correlation with the actual quantities used by the crops. The results indicate nothing definite but simply a difference between a direct action and an adsorption which varies with the nature of the acid and the conditions of the experiment.

It is indicated that a comparison of results with similar soils is useful, but that a comparison of dissimilar soils would involve difficulties. The proper way to use a soil analysis is in conjunction with a soil survey.

A diffusion method in which the reverse reaction is eliminated during acid extraction, thus yielding a true measure of the direct solubility action, is described.

**Notes on the nature of the phosphates contained in mineral phosphates,** G. S. ROBERTSON (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 16-25, figs. 2).—The results obtained from the examination of five different mineral phosphates indicate the presence of three distinct compounds of phosphoric acid and calcium oxid. The formulas of the compounds are submitted.

It was found that the substitution of fluorin or chlorin for the oxygen of one of the CaO groups in the rock phosphates examined did not interfere with the ratio  $P_2O_5:CaO$ . It is indicated that the combination of fluorin or chlorin in this manner would account for the low solubility of rock phosphates in citric acid as compared with bone meal, while the higher lime content of the phosphates would account for their higher solubility in citric acid as compared with apatite. "The results of calcining the various mineral phosphates show that a citric-soluble silica phosphate is formed. This phosphate goes into solution in the first citric extract. In addition to the silica phosphate one or more phosphates with a lower lime content than the original phosphate are produced by calcining. The longer the calcining continues the greater is the tendency to produce phosphates of low lime content, and hence the lower the solubility."

It is further noted that the higher the percentage of lime actually combined with phosphoric acid, the more soluble the mineral phosphate is in citric acid.

**Note on the loss of phosphoric acid during fusion with ammonium fluorid,** W. A. DAVIS and J. A. PRESCOTT (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 136-138).—Experiments with sodium acid phosphate, potassium diacid phosphate, calcium phosphate, and apatite have shown that on ignition with ammonium fluorid a considerable loss of phosphoric acid may occur. The loss is least in the case of salts containing an alkali metal, and greatest in the case of phosphates of the alkaline earth metals, as calcium phosphate or apatite. It is indicated that the phosphorus is probably volatilized in the form of phosphorus fluorid.

**Estimation of calcium in ash of forage plants and animal carcasses,** S. B. KUZIRIAN (*Iowa Sta. Research Bul.* 32 (1916), pp. 99-110).—The following modified procedure is proposed:

The filtrate (acid with nitric acid) from the precipitation of phosphorus as ammonium phosphomolybdate is made ammoniacal and an excess of ammonium oxalate added. The solution is brought to boiling and kept so for 30 minutes, set aside for two hours, and filtered through a Gooch crucible. The precipitate is ignited to convert the oxalates into oxids and cooled rather rapidly by allowing to stand in the air. The contents are then carefully moistened with water over a beaker and dissolved in dilute hydrochloric acid. The contents of the crucible, together with the asbestos, are carefully washed into the beaker, the latter is covered with a watch glass and gently warmed on a water bath or hot plate, and after complete solution filtered through ashless paper and the asbestos carefully washed. Ammonium chlorid is added, and the solution made ammoniacal and boiled for a few minutes until the odor of ammonia becomes faint. The precipitated iron and aluminum are removed by filtration, the filtrate heated to boiling, and the calcium precipitated as oxalate. The calcium is entirely free from molybdenum salts at this stage of the process.

Experiments in which the excess of molybdenum was removed as sulphid showed this step to be of no advantage either in the determination of calcium or in the complete ash analysis.

A comparison of the proposed procedure with the official basic acetate method (E. S. R., 20, p. 512) shows that the new method yields more accurate and concordant results and does not require exact neutrality of the solution. The filtrate from the phosphorus precipitation is small enough so that no evaporation is necessary, the time required for the determination is greatly shortened, and phosphorus and calcium may be determined in the same aliquot.

The basic acetate method is reviewed and certain difficulties encountered by the author in securing concordant results in the later determination of manganese, calcium, magnesium, and the alkalis are pointed out.

Some analytical data of the calcium in the ash of pig carcasses are submitted.

**A new limestone tester, C. G. HOPKINS** (*Illinois Sta. Bul.* 194 (1917), pp. 487-495, fig. 1).—A limestone tester much simpler than the one previously noted (E. S. R., 34, p. 806) and its manipulation are described in detail. The test consists essentially of converting a weighed sample of the limestone into calcium chlorid with dilute hydrochloric acid saturated with carbon dioxid and determining the loss in the reaction. The percentage of calcium carbonate in the original sample is then easily determined by a simple calculation.

Tables showing milligrams of carbon dioxid per cubic centimeter of saturated gas and weight of dry air in milligrams per cubic centimeter of saturated atmosphere, together with some brief notes on limestone samples and the use of limestone for soil improvement, are submitted.

**The determination of humus by means of a simplified procedure of elementary analysis, A. JAKOBSEN** (*Zhur, Opytn, Agron. (Jour. Agr. Expt.)*, 17 (1916), No. 2, pp. 93-98, fig. 1).—A combustion method for the determination of humus in soils, in which platinized asbestos is used as the catalyst, and its manipulation are described in detail. Oxidation with from 1 to 2 gm. of material can be effected in from 25 to 30 minutes, and the results obtained are identical with those obtained by the procedure of Gustavson.

Advantages claimed for the modified procedure are rapidity of combustion, economy of materials, and simplicity in manipulation.

**The estimation of carbohydrates.—V, The supposed precipitation of reducing sugars by basic lead acetate, W. A. DAVIS** (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 7-15).—Continuing previous studies (E. S. R., 33, p. 712), the author submits results which show that, at least in dilute solutions, levulose is never precipitated by basic lead acetate, even in the presence of chlorids, sulphates, or carbonates. There is no loss of levulose unless the excess of basic lead acetate is allowed to act for some length of time on the sugar before the lead is precipitated. Only a slight excess should be used in the defecation of the sugar solution and this excess removed as soon as possible after the precipitation is complete.

It is indicated that basic lead acetate is more effective as a clarifying agent than is normal acetate, and if it is "added carefully in small quantities at a time until the precipitation of the impurities is just complete and the actual excess of the basic lead acetate solution is not allowed to exceed about 5 cc. in 300 to 500 cc. of the solution, there is no loss whatever of levulose or other reducing sugars."

**New contributions to the analysis of milk, E. ACKERMANN** (*Schweiz. Apoth. Ztg.*, 54 (1916), No. 42, pp. 573-578).—Tabular data of the total solids, lactose, lactose-free solids, and refractive index of the serum of normal cows' milk,

milk from animals affected with mastitis, and normal milk diluted with various percentages of water are submitted.

The data show that in normal milk the amount of lactose is usually greater than the amount of lactose-free solids. In animals affected with mastitis the amount of lactose is diminished in the majority of cases, while the amount of protein remains normal. With the addition of water to the milk the amount of the two components diminishes proportionally.

It is indicated that if the amount of lactose alone is abnormal and the lactose-free solids are normal it should not be concluded that the milk is watered, but rather that it comes from an animal or animals affected with mastitis. A table giving the refractive indexes of milk serum at 17.5° C. and from 16 to 41.9° and their respective percentages of lactose is included.

**The composition of cottonseed meal and cotton seed, G. S. FRAPS** (*Texas Sta. Bul. 189 (1916), pp. 5-79*).—This bulletin discusses the composition of cottonseed meal sold in Texas and other States, describes and discusses the method of milling, discusses the effect of milling on the composition of the meal, describes and discusses methods for estimating hulls in cotton seed and for calculating yields of oil and meal from the composition of the seed, and proposes a method for estimating lint on cotton seed, as follows:

About 10 gm. of the whole seed is treated in a beaker with 15 cc. of concentrated sulphuric acid and the contents stirred continuously and thoroughly with a glass rod until all the lint, with the exception of a very little on the tip of the grain, is dissolved. The time for this solution is noted. The seeds are then separated from the excess acid by filtration on a perforated porcelain plate or filter and washed with tap water. They are then spread on ordinary paper and dried for 30 minutes in the steam bath, allowed to remain exposed to the air overnight, weighed, and the percentage of "dissolved lint" calculated. The time of contact with the acid should be reported with the percentage of lint.

Considerable analytical data as regards the composition of the whole seed arranged by location and by varieties, press cake, hulls, etc., are submitted in tabular form.

**Conservation of fruit, fungi, truffles, and vegetables, R. FORLANI** (*Conservazione delle Frutta, dei Funghi, dei Tartufi, e degli Ortaggi. Rocca San Casciano, Italy: Licinio Cappelli, 1915, pp. 207, figs. 7*).—This volume discusses the subject under the following general topics: The harvesting of fruit; conservation in the fresh state; conservation of fruit in the cold; conservation in a dry state; desiccation of oily fruit, etc.; desiccation of vegetables; conservation of fruits and vegetables by sterilization; conservation of fungi and of truffles; and the preparation and industry of green olives.

## METEOROLOGY.

**Report of the chief of the Weather Bureau, 1916** (*U. S. Dept. Agr., Weather Bur. Rpt. 1916, pp. 282, pls. 4*).—This contains (1) an administrative report summarizing the work of the Weather Bureau during the year, (2) a review of weather conditions during 1915 including also sections giving detailed data on sunshine and excessive precipitation, and (3) monthly and annual summaries of pressure, temperature, precipitation, and related data for 1915, and of monthly and seasonal snowfall for 1915-16.

"The most pronounced weather conditions of the year 1915 were the unprecedentedly low temperatures in the southeastern part of the country during the entire month of March, and the unseasonably cool weather over the great cereal and grass-growing States from the middle of May to the last of August. Crop

conditions were generally favorable, except that the growth of corn was greatly delayed by the long-continued cool and wet weather, especially over the northern tier of States, and as a result much of the crop in those districts was injured by frost. The small-grain crops, however, were among the best ever grown, wheat especially making a record yield."

The present and proposed work of the division of agricultural meteorology established February 21, 1916, is quite fully explained. "While a number of new lines of work will be undertaken in this new division, the bulk of its work at the present time comprises former activities now brought together, coordinated, and improved. . . . The division is to conduct investigations of the effect of weather and climate upon the growth and yield of crops and will control the distribution of frost warnings and forecasts to special agricultural interests, conduct studies for the protection of crops and orchards from frosts, and, in general, supervise the activities of the Weather Bureau which relate to agriculture and which are comprised in a number of special services," as follows: Corn and wheat region service, cotton region service, sugar and rice region service, special fruit region service, special tobacco service, special cattle region service, special alfalfa service, and special temperature and storm warnings for sheepmen.

"Studies are going on as to temperature variations at different altitudes in North Carolina, Oregon, Colorado, and Ohio, and investigations have been continued in connection with temperature and frost forecasts for the benefit of those fruit growers who are heating their orchards, and information has been gathered as to the value of these heaters and the expense of orchard protection. . . . Studies to determine the critical period of growth of corn, potatoes, wheat, hay, fruit, and other crops by mathematical and graphical correlation methods" are being continued. Aid has been given the Massachusetts Experiment Station in a study of the weather conditions at different elevations and their effect upon the apple crop and of the relations between inversions in temperature and the development of peach buds.

Preliminary steps have been taken to secure the cooperation of the States generally in determining "the critical period of crops and the weather that has the greatest effect on crop yields, as well as on the extent of insect and fungus damage. It is expected that a definite and extensive system for keeping regular records of the different weather factors and the development of the most important crops will be instituted at a large number of these stations, and such preliminary work started as may be continued through a series of years, and from which large results may be anticipated."

Report of the meteorological station at Berkeley, California, for the year ending June 30, 1915, W. G. REED (*Univ. Cal. Pubs., Geogr., 1 (1917), No. 10, pp. 441-504, figs. 14*).—The results of observations on pressure, temperature, precipitation, etc., are presented in detail for the year.

The average pressure for the year was 30.01 in., about the average for the 28 years of record at this place. The mean annual temperature was 57° F., practically the average for Berkeley. The highest temperature was 94°, September 10; and the lowest, 36°, December 8. The greatest daily range was 41° September 10. September and October were the warmest months, and December was the coldest. Frost was observed on 11 mornings in December and on 3 in January. The total precipitation for the year was 30.95 in., 16 per cent above the average. The total number of days with measurable precipitation was 87, about 30 per cent above the average. The percentage of clear days was 44, of partly cloudy 25, and of cloudy 31. The greatest precipitation on any rainfall day was 1.4 in. Practically all the wind was from a southerly or westerly direction.

Rain and snowfall of Canada, 1903–1913, R. F. STUPART (*Ottawa: Govt., 1914, pp. 207*).—The rainfall and snowfall records published in the annual reports of the Meteorological Service of Canada for the years 1903 to 1913, inclusive, are reprinted and bound together in this report.

Temperature observations during the year 1914, ELIZABETH STEPHANSEN (*Ber. Norges Landbr. Høiskoles Virks., 1914–15, App., pp. 29, figs. 3*).—Daily readings of temperature at Aas, Norway, during 1914 are compared with normals for the period 1874 to 1914. The temperature of the soil at depths of  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $1\frac{1}{2}$  mm. is compared with that of the air.

Temperature changes due to terrestrial radiation and relation of the latter to plant growth, G. ROSTER (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 13 (1916), No. 1, pp. 1–27; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 7, pp. 934, 935*).—This article discusses the question of the placing of thermometers in the open air in order to get readings which are truly representative of the actual temperature conditions to which plants are subjected, and various observations are reported which indicate the wide differences in temperature which may be due to comparatively small differences in the position and elevation of the thermometers. For example, it was observed that a thermometer placed under the dense shade of a carob tree showed minimum temperatures 3 to 4° C. higher than those of a thermometer in the open air. A thermometer 20 in. above the ground receiving all the heat of direct solar radiation as well as soil radiation showed a daily range of temperature approximating 40°. Observations with two thermometers, one 20 in. above the ground and unprotected and the other 55 in. above the ground but protected from the sun and terrestrial radiation, showed the minimum daily temperature in case of the thermometer nearest the ground. The annual mean of 470 observations was 19.2° for the higher thermometer and 16.6° for the lower. The absolute minimum for four years was 11.6° for the first and 6.4° for the second. The monthly mean difference of temperature was 2.3° and the absolute maximum difference was 5.4°.

It is held that “these results prove beyond question the importance of the study, in connection with vegetation, of the temperature changes due to terrestrial radiation, which are perfectly distinct from the general cooling of the atmosphere and occur in the lower air strata, the medium of plant life.”

### SOILS—FERTILIZERS.

Agricultural geology, R. H. RASTALL (*Cambridge, Eng.: University Press, 1916, pp. IX+331, figs. 51*).—The purpose of this book is to supply information on those parts of geology which are of direct interest to the agriculturist. The most space is devoted to a study of the soil, and this is treated primarily from the geological standpoint. The later chapters of the book contain a summary of the distribution of the rock formations of the British Isles and the characters of the soils yielded by them.

On taking samples of soil for soil surveys, E. J. RUSSELL (*Jour. Bd. Agr. [London], 23 (1916), No. 4, pp. 342–349*).—General information on points to be considered in taking soil samples for surveys of English soils are given.

[Soil studies], F. W. MORSE (*Massachusetts Sta. Circ. 64 (1916), pp. 3*).—This circular is intended to supplement Circular 45 of the station (E. S. R., 32, p. 321), and describes a plan by which county agents of the extension service can cooperate with the station in making soil examinations more serviceable. It is considered especially desirable to compare the texture and composition of soils of known value for special crops with those of soils believed to have similar possibilities. A method of sampling with a soil auger to be uniformly used is described, and an outline of factors useful in soil classification is given.

Soil survey of Yell County, Arkansas, E. B. DEETER and C. LOUNSBURY (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 41, fig. 1, map 1*).—This survey, issued January 10, 1917, deals with the soils of a naturally well drained area of 603,520 acres in west-central Arkansas. A large proportion of the county includes mountains, and relatively broad, level to gently rolling intervening valley areas constitute the principal farming land. The upland soils, comprising more than 80 per cent of the area, are of residual origin and consist largely of loams, sandy loams, and stony loams. Including rough stony land and riverwash, 23 soil types of 12 series are mapped, of which the Hanceville stony loam, rough stony land, Hanceville loam, and Conway silt loam cover 33.2, 14.9, 14.8, and 12.1 per cent of the area, respectively.

Composition of Hawaiian soil particles, W. T. McGEORGE (*Hawaii Sta. Bul. 42 (1917), pp. 12*).—A study of the composition of the coagulable and non-coagulable clay grains and an investigation on the composition of the clay, fine silt, silt, fine sand, and coarse sand separates in the important types of Hawaiian soils are reported. The origin of Hawaiian soils and the changes which these soils undergo during disintegration are also discussed.

A wide variation was found in the composition of soil particles of the same size from different Hawaiian soil types. This variation is attributed primarily to the number and intensity of action of the several weathering agents which are instrumental in the disintegration of the lava. "Iron, titanium, and manganese are present in largest amount in the coarse grains. Silica, alumina, and phosphoric acid predominate in the finest particles; lime and magnesia in the coarse grains. The influence of coagulants upon Hawaiian clays varies with the composition of the clay. Those most difficultly coagulable are higher in iron and silica than those readily coagulable."

Summary of Illinois soil investigations, C. G. HOPKINS, J. G. MOSIER, and F. C. BAUER (*Illinois Sta. Bul. 193 (1916), pp. 450-484, pl. 1, figs. 6*).—This bulletin summarizes the results of soil investigations which have been carried on in Illinois since 1901, including systematic soil surveys, chemical analyses, and cultural experiments. Illinois soils exist in 14 great soil areas and in the counties covered by the first 10 soil reports, 62 individual and extremely diverse soil types have been discovered and grouped into 6 classes as prairie, timber, terrace, ridge, swamp and bottom land, and residual soils.

"Fertility invoices of the individual soil types show a great variation in the content of the essential plant-food elements. Illinois soils may be deficient in one or more of five plant-food elements, namely, nitrogen, phosphorus, potassium, calcium, and magnesium, and they may be either acid or alkaline. Thus the problem of maintaining the fertility of the soil is sometimes complicated, though usually limited essentially to the application of limestone and phosphorus and the turning under of nitrogenous organic matter.

"As a rule, the results of the field experiments harmonize with the information given by the chemical composition of the soil. They have shown (1) that the maintenance of organic matter and nitrogen is the greatest practical problem of the Illinois farmer, (2) that phosphorus is the one element of plant food that is most universally deficient, and (3) that limestone must be supplied in abundance to many soils before they can be permanently improved. On the ordinary corn-belt soil, proper treatment has produced a total value for one rotation (1911-1914) of \$98.58, as contrasted with \$65 where no treatment was given. One dollar invested in rock phosphate has paid returns as follows: First rotation, \$1.18; second rotation, \$1.62; third rotation, \$2.70. . . .

"Southern Illinois prairie land has been improved by proper soil treatment so that the total increase over untreated land has been 207 per cent. On peat soil, potassium has increased corn yields by more than 30 bu. per acre. On sand

soils during six years the value of the crops per acre has been increased \$73.37 by nitrogen and only 22 cts. by phosphorus in addition."

A list of 34 available publications relating to Illinois soil investigations is appended.

**Tazewell County soils**, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRETT (*Illinois Sta. Soil Rpt. 14 (1916)*, pp. 68, pls. 2, figs. 11).—This is the fourteenth of the Illinois county soil reports.

Tazewell County is located a little north of the central part of the State, principally in the earlier Wisconsin glaciation. The general topography of the county is gently rolling with the exceptions of the northwestern and eastern parts, where small streams have broken the upland into a series of hills and valleys. Natural underdrainage exists over a large part of the gravel terrace. An area in the southwestern part of the county needs artificial drainage.

The soils of the county include (1) upland prairie soils rich in organic matter, (2) upland timber soils, (3) terrace soils, and (4) swamp and bottom lands, covering, respectively, 37.62, 24.91, 22.01, and 14.36 per cent of the area. The brown silt loam is the most extensive single type. "The most significant facts revealed by the investigation of the Tazewell County soils are the lack of limestone and the low phosphorus content of the common prairie soil and of the most extensive timber types, which combined cover nearly 60 per cent of the entire county."

**The principal soil areas of Iowa**, W. H. STEVENSON (*Iowa Yearbook Agr., 16 (1915)*, pp. 581-592, fig. 1).—This report states that there are four distinct classes of soils in Iowa, geest, alluvium, loess, and till. The two latter are the most important, comprising about 93 per cent of the area of the State. There are three distinct areas of loess soil, the Missouri loess in western Iowa, the Mississippi loess in eastern Iowa, and the loess of southern Iowa. There are three distinct areas of glacial till, the Wisconsin, the Iowan, and the Kansan.

The principal soil problems of these different areas are as follows: (1) Drainage, which affects especially the Wisconsin drift area and the wide river bottoms, and in a lesser degree the Iowa drift area and the hilly Kansan drift area in southern Iowa; (2) treatment of the so-called alkali spots of the newer drift areas; (3) treatment to restore the fertility of the leachy areas of the loess and the Iowan drift area; (4) treatment of the gumbo, the geest, the ferretto, and the clay hills of southern Iowa according to the special requirements of the different cases; (5) prevention of soil erosion, which is the source of enormous loss to Iowa and a constant menace in the hilly regions; (6) treatment to cause the loess soils to warm up more quickly in the spring; (7) experiments to find the difference in productivity shown by certain areas as regards certain crops and to find how these differences may be equalized; and (8) experiments to determine the most practicable system of crop rotation for each principal area.

**Soil survey of Grenada County, Mississippi**, W. E. THARP and J. B. HOGAN (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915*, pp. 32, fig. 1, map 1).—This survey, made in cooperation with the State of Mississippi, and issued January 27, 1917, deals with the soils of an area of 284,160 acres in north-central Mississippi, the greater part of which consists of rolling to hilly uplands, in places very rough. The western end of the county lies in the Mississippi flood plain.

"The upland soils of the western and central parts of the county are of loessial origin. In the eastern half of the county the loess is seldom more than a few feet deep, and the underlying coastal plain material, consisting mostly of sand and clay, enters largely into the composition of the soils."

Including meadow, 14 soil types of 11 series are mapped, of which the Grenada silt loam, Lexington silt loam, and Vicksburg silt loam cover 24.9, 13.2, and 12.7 per cent of the area, respectively.

Soil survey of the Bitterroot Valley area, Montana, E. C. ECKMANN and G. L. HARRINGTON (*U. S. Dept. Agr. Advance Sheets Field Operations Bur. Soils, 1914, pp. 72, pls. 3, fig. 1, map 1*).—This survey, issued January 18, 1917, deals with the soils of an area of 327,040 acres in Ravalli and Missoula counties in western Montana. The valley area is a well marked depression of structural origin. The soils of the area have been derived from residual material, ice-laid and water-laid glacial material, old valley filling deposits, recent alluvial fan material, recent alluvium, and miscellaneous materials. Fifteen soil series, embracing 36 soil types, and two miscellaneous soils are recognized in the area. Of these, rough stony land covers 17.3 per cent, Bass stony sandy loam 9.1 per cent, Burnt Fork stony loam and Victor stony sandy loam each 7.8 per cent, and Waterloo sandy loam 6.5 per cent of the area.

Geology of Cincinnati and vicinity, N. M. FENNEMAN (*Geol. Survey Ohio, 4. ser., Bul. 19 (1916), pp. 207, pls. 14, figs. 59*).—This report contains physiographic data which may be of use in a study of the soils of Ohio.

Soil survey of Dorchester County, South Carolina, W. J. LATIMER, J. M. SNYDER, and C. VAN DUYNE (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 45, pls. 2, fig. 1, map 1*).—This survey, issued January 16, 1917, deals with the soils of an area of 362,240 acres in the Coastal Plain region of southeastern South Carolina, the surface of which is level to gently rolling. "The northern half of the county is higher and, in general, better drained than the southern part, where there are extensive areas of flat savannas and low-lying, poorly drained land. The bottom lands along the streams are wide and the streams sluggish. . . .

"The soils of Dorchester County are divided into three classes: (1) Upland or sedimentary soils, consisting of unconsolidated Coastal Plain sands and clays, derived originally from the Piedmont Plateau and the Appalachian Mountains, (2) terrace . . . soils lying above overflow, consisting of old alluvial material derived from the Coastal Plain soils, and (3) first-bottom . . . soils." Including tidal marsh, 27 soil types of 10 series are mapped, of which the Johnston loam, Norfolk sandy loam, and Norfolk fine sandy loam cover 15.4, 11.8, and 10.7 per cent of the area, respectively.

Soils of Grayson, Lee, McLennan, Titus, and Tyler counties [Texas], G. S. FRAPS (*Texas Sta. Bul. 192 (1916), pp. 51*).—This bulletin contains a description of soil types in the counties named, based on surveys by the Bureau of Soils of the U. S. Department of Agriculture previously noted (E. S. R., 16, p. 1059; 19, p. 417; 26, p. 718), together with chemical analyses of representative samples and a discussion of their fertility requirements based in part on pot experiments.

The soils of Grayson County, covering 1,010 square miles consisting mainly of black prairie lands, were found to be well supplied with total phosphoric acid but low in available phosphoric acid. A number of the soils are low in nitrogen. It is concluded that these soils require legume rotation and the application of acid phosphate.

The soils of Lee County, covering about 700 square miles, were found to be for the most part deficient in active phosphoric acid and nitrogen. Nitrogen and acid phosphate applications and crop rotations are recommended for these soils.

The soils of McLennan County surveyed, covering 440 square miles, were found for the most part to be well supplied with phosphoric acid, nitrogen,

and potash, and fairly well supplied with lime. Crop rotation appeared to be the principal requirement of the soils.

The soils of Titus County, covering 426 square miles, were found to be relatively deficient in nitrogen and lime. The active and total phosphoric acid contents were low in some cases.

The soils of Tyler County surveyed, covering 100 square miles, were found to be acid and relatively deficient in nitrogen and potash and with one exception in phosphoric acid.

Soil survey of Smith County, Texas, L. R. SCHOENMANN, E. H. SMITH, W. A. ROCKIE, E. T. MAXON, F. Z. HUTTON, and H. G. LEWIS (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 51, fig. 1, map 1*).—This survey, issued January 23, 1917, deals with the soils of an area of 570,880 acres in the Gulf Coastal Plain region in northeastern Texas, the topography of which is gently rolling to moderately hilly. "Only a small part of the county is too rough for cultivation, and a still smaller part is so smooth and level as to possess poor natural drainage."

The soils are grouped as upland and lowland soils. "More than 75 per cent of the upland consists of fine sands, fine sandy loams, and gravelly sandy loams, with subsoils ranging from fine sand through fine sandy clay to stiff, heavy clay. The clay soils are comparatively insignificant in extent, but the clay loams and gravelly clay loams are fairly extensive. The greater part of the first-bottom soils consists of clay and silty clay loam, but the fine sandy loams have an important distribution. The second-bottom, or terrace, soils are sandy and rather small in extent."

Including meadow, 22 soil types of 13 series are mapped, of which the Ruston fine sandy loam, the Susquehanna fine sandy loam, and the Norfolk sand cover 22.7, 21.9, and 18 per cent of the area, respectively.

Soil survey of Franklin County, Washington, C. VAN DUYNE, J. H. AGEE, and F. W. ASHTON (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 101, pls. 2, figs. 7, map 1*).—This survey, made in cooperation with the State of Washington and issued January 13, 1917, deals with the soils of an area of 786,560 acres in south-central Washington. The eastern part of the county is high rolling plateau and the western part undulating desert plain. "Over the greater part of the county there is no surface run-off, the water being removed by seepage and evaporation." The soils of the county are derived from a mantle of lake laid, wind laid, loessial, and current laid material. Including four types of miscellaneous character, 30 soil types of 12 series are mapped, of which the Ritzville silt loam, Ephrata very fine sandy loam, and scabland cover 31.3, 14.2, and 9.3 per cent of the area, respectively.

Calcium compounds in soils, E. C. SHOREY, W. H. FRY, and W. HAZEN (*U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 3, pp. 57-77*).—This report presents analytical data bearing on the kinds of calcium compounds in 63 samples of soil representing 23 types from 24 locations in 19 States. The quantities of calcium carbonate, calcium sulphate, calcium combined with humus compounds, and calcium present as easily and difficultly decomposable silicates are calculated.

The results show "a wide variation in total calcium content and in content of calcium carbonate and the two classes of silicates. Calcium combined with humus compounds is shown to be absent in 29 samples. No relation is apparent between the total calcium content and the quantity of any of the classes of calcium compounds discussed. It is shown that it is possible to have two soils with the same calcium content, but with the kinds of calcium compounds present in quite different quantities. But five of the samples, representing two types, were acid to litmus. These types are characterized by

poor drainage. A type represented in this series, recognized as a good alfalfa soil, is characterized by a high calcium content, but low in content of calcium carbonate."

Studies of the lime requirements of certain soils, L. J. WILD (*Trans. and Proc. New Zeal. Inst.*, 48 (1916), pp. 513-517).—Tests of the Hutchinson and MacLennan method of determining the lime requirement of soil, which is based on the absorptive capacity of the soil for calcium carbonate presented to it in solution as bicarbonate (*E. S. R.*, 33, p. 622). showed that the method gives results for a given soil which agree sufficiently with what is known from other sources of the lime requirements of that soil for practical purposes.

"It has been shown, however, that the result for any given soil varies with the strength of the solution and that in practice it is necessary to make the determination under standard conditions. Either a solution of uniform strength must be employed for all determinations or a correcting factor must be applied."

The phenomenon of absorption in its relation to soils, J. A. PRESCOTT (*Jour. Agr. Sci. [England]*, 8 (1916), No. 1, pp. 111-130, fig. 1).—This is a critical review of investigations on this subject, dealing with the general facts of absorption, Way's chemical hypothesis, Liebig's physical hypothesis, Knop's compromise and analytical method, absorption of acid radicals, effect of temperature on absorption, absorption by humus, the conception of colloids, adsorption, and adsorption isotherms. Particular attention is given to the applications of absorption phenomena to soils.

The definition of soil fertility by means of the analysis of plants, P. SAVVIN (SAWINE) (*Zhur. Opytn. Agron. (Jour. Agr. Expt.)*, 17 (1916), No. 1, pp. 1-12; *abs. in Chem. Abs.*, 10 (1916), No. 22, pp. 2950, 2951).—Experiments are reported, the results of which are taken to indicate the following:

Oat grains contain phosphoric acid almost exclusively in organic combinations. Phosphates are generally in the straw. The percentage of organic phosphoric acid in an entire plant varies between very narrow limits, which experimentally were found to be from 0.41 to 0.6 per cent. The size of harvest does not influence this, and the amount of phosphoric acid which has entered the plant influences it only to a small degree. If phosphoric acid is abundant in the nutritive solution it enters into the plant in greater quantity, but it is only an insignificant part which takes an organic form, the greater part entering the straw as phosphates. The quantity of phosphates in the straw varies according to the conditions of a given vegetative period. It is concluded that for this reason the conditions relating to phosphoric acid can not be used for indicating soil fertility. The total phosphoric acid in the straw and in the entire harvest can, however, indicate the need for phosphatic fertilization.

Certain biological chemical processes in relation to the humification of plant residues, A. TRUSOV (TROUSOFF) (*Zhur. Opytn. Agron. (Jour. Agr. Expt.)*, 17 (1916), No. 2, pp. 165-179, figs. 8).—The various processes and products involved in humification and the complex mixture known as humic acid are discussed.

Studies on soil protozoa and their relation to the bacterial flora, I, II, J. M. SHERMAN (*Jour. Bact.*, 1 (1916), Nos. 1, pp. 35-66; 2, pp. 165-185).—Studies conducted at the Wisconsin Experiment Station on the life and activities of soil protozoa, with special reference to their influence on the numbers of soil bacteria, are reported.

In the soil studied the flagellates were the predominating type of protozoa. *Colpoda cucullus* appeared to be the most widely distributed ciliate. It was found that the ciliates *C. cucullus*, *Balantiophorus elongatus*, and *Oxytricha* sp. are not active under ordinary soil conditions. The bacterial flora in soils containing protozoa and free of protozoa behaved in exactly the same way when

exposed to different conditions of temperature and moisture content. The ciliates *C. cucullus* and *B. elongatus* in pure culture were detrimental to bacteria in solutions but not in soil. Four types of active soil flagellates were not capable of limiting the number of bacteria when acting in soil, but one culture was injurious to bacteria in soil extract.

Treatment of soil with the ordinary amounts of volatile antiseptics (1 to 2 per cent) did not appear to simplify the protozoan fauna, and as much as 10 per cent of carbon bisulphid or toluene failed to exterminate the protozoa entirely. Within one month after treatment normal numbers of protozoa were again present in the soil. The maximum number of bacteria in partially sterilized soil was not found while the protozoa were suppressed but after they had again returned to their normal level. It appeared that the development of these two classes of micro-organisms subsequent to treatment with volatile antiseptics ran parallel. The re inoculation of partially sterilized soils with 1 per cent of normal soil failed to decrease the number of bacteria.

"The results of the foregoing experiments appears to establish quite definitely that protozoa in the soils which have been studied do not have a detrimental effect upon the bacterial flora."

A list of 70 references to literature bearing on the subject is appended.

The disinfection of soil, É. MIÈGE (*Assoc. Franç. Avanc. Sci., Compt. Rend.*, 43 (1914), pp. 978-982).—This is a summary of the results of the work of others bearing on the subject.

Rotation and manure experiments on the Wisconsin drift soil area, W. H. STEVENSON and P. E. BROWN (*Iowa Sta. Bul.* 167 (1916), pp. 462-476, figs. 8).—Six-year rotation and manuring experiments on Carrington loam soil are reported. The rotation experiments were carried out on 13 1/10-acre plats and the rotations were as follows: Continuous corn; 2-year rotation, corn and oats; 3-year rotation, corn, oats, and clover; 2-year rotation, corn and oats, clover turned under; 2-year rotation, corn and oats, cowpeas turned under; 2-year rotation, corn and oats, rye turned under; and continuous clover. The manuring experiments were conducted on 20 1/10-acre plats and the manure used at rates of 8, 12, 16, and 20 tons per acre.

It was found that the continuous growing of crops on this soil decreases its fertility and leads to rapidly declining crop yields, while the rotation of crops gives greater profit than the continued growth of corn. "A 3-year rotation of corn, oats, and clover is more profitable than a 2-year rotation of corn and oats, or a 2-year rotation with clover, cowpeas, or rye used as a green manure crop. The introduction of clover, cowpeas, and rye into a 2-year rotation increases the crop yields, but it can hardly be considered profitable except in the case of the clover. The profit is less, however, in every case than in the 3-year rotation.

"The best amount of manure to apply to this type of soil appears to be between 8 and 16 tons per acre, applied once in a 4-year rotation. Applications of more than 16 tons of manure per acre are not profitable. Manure applied in three equal amounts in the first, second, and fourth years of the 4-year rotation proved of greater value on this soil than the same total amount applied once in the rotation. Manure should not be applied to this soil after the corn crop is up, as very much smaller effects are secured from its use than when it is plowed under or disked in after plowing. On this soil type the latter method seems to be slightly preferable."

A modified method of green manuring, C. M. HUTCHINSON (*Agr. Research Inst. Pusa Bul.* 63 (1916), pp. 12).—Field experiments are reported which confirm the conclusions from results of laboratory tests given in a previous bulletin

tin (E. S. R., 31, p. 722) "that green crops instead of being plowed or buried by other methods directly in the soil on which they had been grown, should first be treated in such a way as to bring them into a more suitable condition for use as manure." Tests were made of methods of doing this with sann hemp as follows: "(1) Aerobic, in which the green manure was fermented in heaps, kept moist but not covered with clay, [and] (2) anaerobic, in which the heaps were plastered with clay. The sann hemp was first cut into short lengths and soaked in water in a pit for 24 hours. It was then removed from the pit and transferred to another shallow one, in this case about 1 ft. deep and 8 ft. square."

In aerobic fermentation "the soaked material was arranged in alternate layers of sann and soil, the former about 3 in. and the latter about 0.5 in. in thickness. The whole heap was then covered with a layer of soil about 3 in. thick and finally with one of straw to prevent evaporation. Watering was carried out about once a week, sufficient water being added to keep the top layer moist. [In] anaerobic fermentation the heaps were arranged in the same way, but each layer was consolidated by treading down, and the whole heap was finally plastered with clay about 1 in. thick." After 48 days the heaps were broken down and the material applied to experimental plats of tobacco either in furrows or ridges. The results indicated a decided superiority of the aerobically fermented manure applied in the furrows.

"With regard to the difference in character of the anaerobic and aerobic preparations, it was found that when first taken from the heap the former contained no nitrate but a considerable amount of ammonia (recoverable by distillation with magnesia although not free). A water extract of the material was toxic to seedlings, but this condition was changed and nitrate formation took place after aerobic conditions were introduced, more complete nitrification of the organic nitrogen present being eventually obtained than was the case with the aerobically prepared material. This was in accordance with the laboratory observations of the previous year, and confirms the conclusion as to the possibility of preparing a more rapid acting manure by this method, keeping in view, however, the necessity for interposing an aerobic stage between the anaerobic preliminary one and the final application to the soil, not only to promote nitrification, but to insure the oxidation and destruction of the toxins produced."

A note by S. Milligan especially on the economic feasibility of the proposed method is included.

**Peat in 1915**, J. S. TURP (*U. S. Geol. Survey, Mineral Resources of the United States Calendar Year 1915, pt. 2, pp. 1027-1030*).—This report deals with the production and use of peat in the United States during 1915.

"The production of peat for fertilizer and fertilizer filler during 1915 was 38,304 short tons, valued at \$258,447, as compared with 37,729 short tons, valued at \$249,899, in 1914. . . . The lowest price per ton reported was \$3, the highest \$16 and the average \$6.75." The entire importation of peat litter in 1915 was 7,514 short tons, valued at \$48,142.

**Some sources of potassium**, C. T. HIRST and E. G. CARTER (*Utah Sta. Circ. 22 (1916), pp. 3-12*).—This circular deals briefly with the function of potash in plant nutrition, the German potash deposits, and the consumption of potash in the United States, but discusses more particularly the actual and possible sources of potash in the United States, including especially alunite, leucite, material from nitrate deposits near Rigby, Idaho, material from the bed of an old alkali lake, and the ash of various desert plants. Analyses of the material from the nitrate deposit, the lake bed, and of the ash of the desert plants are

reported. The amounts of potash in the dry plant were found to be as follows: Sage brush 0.43 per cent, white sage 1.64, rabbit brush 0.75, Brigham tea 0.35, and greasewood 0.96.

**Potash as a by-product from the blast furnace, R. J. WYSON** (*Bul. Amer. Inst. Mining Engin., No. 121 (1917), pp. 1-32, figs. 20*).—Data showing the amount of alkalis, especially potash, occurring in the raw materials and in the slag, cinder, dust, fumes, etc., of the blast furnaces of a large steel works are reported and discussed with reference to the feasibility of recovering the potash for sale.

It is stated that with the gas-cleaning methods now used in the blast furnaces there is a loss in the primary washers alone of over one-half of the total potash charged, or from 9 to 12 lbs. per ton of pig iron produced. The amount recovered by these methods is less than 2 per cent of the total. About two-thirds of the total potash charged is now lost in the wash water and stack gases, or about 15 lbs. per ton of pig iron produced. Experiments with an electric dust precipitator showed that practically all the dust and fume entering the treater can be successfully precipitated by this means. The precipitated dust was found to contain about 10 per cent of potash. It is suggested that while weak acid treatment may be effective in making the potash of the flue dust soluble it is not likely to be practicable, but that the soluble alkali salts can be recovered in tolerably pure form by leaching and evaporation.

The author is of the opinion "that in the future dry cleaning will be adopted in many blast furnace plants, and that many thousands of tons of potash hitherto wasted will be reclaimed."

A bibliography of the more important articles bearing on the subject is appended.

**Potash becomes a valuable cement mill by-product, A. C. HEWITT** (*Engin. News, 76 (1916), No. 26, pp. 1222-1226, figs. 5*).—This is a description of a dust precipitation plant of a cement mill at Hagerstown, Md., which not only reduces the dust nuisance, but is said to be profitable for its production of potash. At the present time, with two kilns 7 by 100 ft. and three kilns 8 by 125 ft., the production of potash dust is said to average from 20 to 25 tons per 24 hours, containing approximately 10 to 20 per cent of potassium sulphate.

**The effect of additions on the availability of soil potash, and the preparation of sugar humus, G. S. FRAPS** (*Texas Sta. Bul. 190 (1916), pp. 30*).—Four series of experiments are reported on the effect of additions of calcium carbonate, sawdust, sugar humus, corncobs, calcium sulphate, sodium sulphate, sheep manure, and magnesium carbonate on the quantity of potash taken up by crops of corn, cotton, sorghum, and oats from eleven soils, including Norfolk sand, bottom land soil, sand, Norfolk fine sand subsoil, brown mesquite soil, white sand, very poor upland soil, moderate upland soil, poor upland subsoil, poor upland soil, and Norfolk white sandy loam subsoil.

It was found that gains of potash due to the addition of calcium carbonate or organic matter were comparatively small. The active potash of the soil needed no addition of calcium carbonate, as it was already highly available. Sodium sulphate and gypsum were often injurious. Plants were found to take up an excess of potash over their actual needs. The percentage of potash in the plants decreased as the amount of active potash in the soil decreased. Additions of calcium carbonate did not increase the quantity of active potash remaining in the soil at the end of the experiments.

"The quantity of active potash lost is from 60 to 90 per cent of that taken up by the crop, until the active potash is reduced so that the potash removed actually comes from insoluble potash compounds and not from the active potash. Active potash may be readily and rapidly removed by crops down to the quan-

tity representing the potash from highly insoluble compounds. Additions of sulphate of lime, nitrate of soda, or other salts have no such effect upon rendering potash available to plants as has been claimed. They would have only a slight effect."

A study of conditions affecting the yield of sugar humus is also reported and a method of preparing it described.

**Solubility of mineral phosphates**, A. AITA (*Ann. Chim. Appl. [Rome]*, 6 (1916), No. 1-2, pp. 28-44, fig. 1; *abs. in Chem. Abs.*, 10 (1916), No. 22, pp. 2953, 2954).—Consecutive extractions with 2 per cent citric acid made on different types of phosphates showed that nodulous and hard phosphates gave up their phosphoric acid more slowly than the more friable varieties, seven or eight extractions being required for the former.

With reference to the influence of the calcium oxid content, it was found that in the first extraction the percentage of phosphoric acid extracted increased as the calcium oxid content decreased. In the successive extractions the percentage of phosphoric acid extracted continually increased in the case of high calcium oxid content, with the order of the extraction as the calcium oxid disappeared under the action of the citric acid. With phosphate of low calcium oxid content the opposite occurred in subsequent extractions. Ignited phosphates gave up their phosphoric acid more slowly than the natural minerals.

In studies of the solubility of mineral phosphates in 2 per cent citric acid in the presence of salts, two consecutive extractions were made. It was found that (1) calcium salts diminished the solubility, (2) ammonium, alkali, and magnesium salts brought about an increase of solubility proportionate to their concentration and dependent on the factors of friability, fineness, and calcium oxid content, and (3) the increase of solubility was a function of the anion. The author attempts to explain these results, and draws the conclusion that finely ground mineral phosphates may be used in agricultural practice as substitutes for basic phosphates if they are accompanied either at the time of spreading over the soil or during growth of the vegetation by fertilizers of ammonium, potassium, or soluble magnesium salts.

The utilization of phosphates by agricultural crops, including a new theory regarding the feeding power of plants, E. TRUOG (*Wisconsin Sta. Research Bul.* 41 (1916), pp. 50, figs. 14).—Supplementing experiments previously reported (*E. S. R.*, 27, p. 127), pot culture experiments were made with corn, oats, barley, millet, turnips, rape, buckwheat, clover, alfalfa, serradella, sunflowers, and tobacco to test the availability of acid phosphate, rock phosphate, ferrous phosphate, ferric phosphate, tricalcium phosphate, aluminium phosphate, manganous phosphate, and trimagnesium phosphate. In the case of corn the effect of different nitrogenous compounds, namely, calcium, ammonium, sodium, and potassium nitrates, was also tested. The degree of utilization of the phosphates was measured both by the yield and the phosphorus content of the crops grown.

It was found that "the different species of plants showed some marked individual preferences for the different phosphates. Solubility of the phosphates was not the only factor that determined the growth of a plant on these phosphates. Precipitated ferric and aluminum phosphates produced with a few exceptions good growths and in a few cases even better growths than the acid phosphate. The availability of these phosphates is undoubtedly due to ease of hydrolysis of the neutral or nearly neutral material, in which case the phosphoric acid goes into solution and there is left a basic phosphate. . . . The phosphorus of precipitated tricalcium phosphate was much more available than that of rock phosphate, although the form of phosphate is perhaps nearly the same in the two." The author attributes this to the greater ease of

hydrolysis of the freshly precipitated form of phosphate, due partly to the better physical condition.

Great differences in the feeding powers of the different plants were observed. It was found, as is shown in a previously noted article (E. S. R., 33, p. 519), that plants containing a relatively high calcium oxid content showed a relatively high feeding power for the phosphorus in raw rock phosphate, while for plants containing a relatively low calcium oxid content the reverse was true. The theory advanced to explain the variation in the feeding power of plants for difficultly soluble phosphates (and other substances) is summarized as follows:

"Each point of contact or near contact between the absorbing surface of root hairs and difficultly soluble substances may be regarded as a chemical system which strives to attain a point of equilibrium between liquid and solid phases. In this system carbonic acid and water are the main agents causing solution. In some cases the action is largely one of hydrolysis and there is formed a soluble product and an insoluble product, e. g., action of water on ferric phosphate; in other cases the action may be both by hydrolysis and carbonation and the products formed are both soluble, e. g., action of carbonated water on calcium phosphate; or only one of the products may again be soluble, e. g., action of carbonated water on feldspar.

"In order that the solubility reaction may continue in any of the cases, it is necessary that proportionate amounts of all the soluble products be continually removed. Thus, if a plant is to feed strongly on rock phosphate, both the calcium acid phosphate and calcium bicarbonate must be used by the plant in somewhat proportionate amounts. In this case the calcium oxid content of the plant becomes the determining factor in the feeding power."

"The increased availability of rock phosphate when used in connection with ammonium salts is explained by this theory as due at least partly to the increased solubility of the calcium carbonate and bicarbonate in solutions of ammonium salts. The greater availability of rock phosphate in acid soils than in nonacid soils, especially to plants with weak feeding powers, is also explained, since acid soils will remove the calcium carbonate and bicarbonate from solution and thus make it possible for the solubility reaction to continue."

It is pointed out that since the roots of plants at any one time come in contact with only a small portion of the internal surface of the soil, and the feeding of plant roots therefore probably takes place largely in local soil areas, the rate at which phosphorus goes into solution in the local areas in contact with the roots is a more important consideration than the amount of it which may be drawn off from the whole soil mass in one extraction.

It was observed in these experiments that plants grown with magnesium phosphate had an exceptionally high content of phosphorus, thus supporting Loew's hypothesis (E. S. R., 15, p. 227) that magnesium functions as a conveyor of phosphorus in the plant. A high calcium oxid content was found in certain cases to be associated with a high protein content, thus indicating an important function of calcium in protein synthesis. Plants grown with manganous phosphate were found to contain considerable amounts of manganese, and since manganese affects the chlorophyll formation of certain plants, especially of clover and alfalfa, it is suggested that the poor growth of these plants on certain acid soils may be due to the presence of considerable amounts of manganese.

**Report on commercial fertilizers, 1916, E. H. JENKINS and J. P. STREET** (*Connecticut State Sta. Rpt. 1916, pt. 1, pp. 1-63*).—This bulletin contains the results of actual and guaranteed analyses of 828 samples of fertilizers and fer-

tilizing materials offered for sale in Connecticut in 1916, together with analyses of 10 samples of tobacco soils, made with the object of studying the cause of the unsatisfactory yield of tobacco from certain soils.

Tabulated analyses of commercial fertilizers, W. FREAR ET AL. (*Penn. Dept. Agr. Bul. 282 (1916), p. 75*).—This report contains the results of actual and guaranteed analyses and valuations of 816 samples of fertilizers and fertilizing materials collected for inspection in Pennsylvania from January 1 to August 1, 1916.

Commercial fertilizers in 1915-16, G. S. FRAPS (*Texas Sta. Bul. 193 (1916), pp. 3-23*).—This bulletin reports the results of actual and guaranteed analyses of 291 samples of fertilizers and fertilizing materials collected for inspection in Texas during 1915-16. A list of brands registered for sale in the State is also included. Attention is called to the fact that Texas soils are as a rule well supplied with potash, and that potash can therefore be eliminated from general fertilizers, especially for cotton and corn.

### AGRICULTURAL BOTANY.

Plants in health and disease, F. E. WEISS, A. D. IMMS, and W. ROBINSON (*Manchester: University Press; London and New York: Longmans, Green and Co., 1916, pp. VIII+143; rev. in Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 4 (1916), p. 112*).—This is a reprint in book form of lectures delivered at the University of Manchester during the session 1915-16 on plant life, animals injurious or beneficial thereto, and the nature, progress, and control of plant diseases, more particularly as relating to conditions prevalent in Manchester, England, during the present period with its unusual needs. The scientific information embodied is presented in popular form for purposes directly practical, and a few references are given to related literature, mostly on the zoological side.

The raw materials of the plant kingdom, J. VON WIESNER (*Die Rohstoffe des Pflanzenreiches. Leipzig and Berlin: W. Engelmann, 1914, 3. ed., rev. and enl., vol. 1, pp. X+759, figs. 98*).—This is the first of the three volumes of which this third edition (E. S. R., 12, p. 996), when completed, is to be composed. The 10 sections of this volume deal, respectively, with gums, resins, caoutchouc, opium, aloes, camphor, indigo, catechu, vegetable fats, and vegetable wax, concluding with a detailed alphabetical list of the various substances included under the above heads.

Physiological characters of plants.—II, Oils and alkaloids of Papaveraceæ; III, Oils and alkaloids of Ranunculaceæ and Berberidaceæ, S. L. IVANOV (*Soobshch. Bûro Chastn. Rast. [Petrograd], 2 (1915), No. 7, pp. 25-38*).—Incomplete studies have shown that the presence of various oils and alkaloids is not confined to *Papaver somniferum*, but that oils of certain Ranunculaceæ may prove to be of great commercial value, particularly on account of their high melting point.

The overlapping of the leaf sheath and its lack of value for descriptive botanical literature, A. B. CONNER and R. E. KARPER (*Science, n. ser., 45 (1917), No. 1154, pp. 144, 145*).—From a study of milo maize and Kafir corn grown under different environmental conditions, the authors have found that internodal length varies widely and that there is little variation in the length of the leaf sheath. On this account, it is claimed that the overlapping of the leaf sheath can not be considered a character of value in descriptive botany.

A contribution to the problem of homotyposis, J. A. HARRIS (*Biometrika, 11 (1916), No. 3, pp. 201-214, figs. 4*).—The data on *Cercis canadensis* presented in this paper are drawn from records of work begun in 1905 and already con-

sidered more comprehensively in dealing with problems distinct from the one here discussed (E. S. R., 31, p. 523). The results as tabulated are discussed in connection with some obtained by other investigators.

It is stated that the average homotypic value for ovules in *Cereis* is distinctly higher than the comparable values for other species hitherto adequately investigated, the mean values for seeds being about the same as those found by English investigators. The correlation of ovules falling is lower. The homotypic correlation for seeds matured per pod is statistically largely a resultant of the homotypic correlation for ovules and the organic correlation for ovules and seeds of the same pod. There are supposed to be independent ecological and physiological factors tending to differentiate individuals with respect to capacity for seed production. The general rule for fertility characters in Leguminosæ apparently is that the maximum value of the homotypic correlation is the same as that for number of ovules per pod, much lower values being found for matured seeds or abortive ovules per pod. The author believes that the evidence also points in the direction of a lower correlation for ovules than for the more truly vegetative characters of the plant.

Inheritance in crosses between *Nicotiana langsdorffii* and *N. alata*, E. M. EAST (*Genetics*, 1 (1916), No. 4, pp. 311-333, figs. 10).—Reporting on a study of a fertile cross between *N. langsdorffii* and *N. alata grandiflora*, each uniform in its characters, the results being the same without regard to the direction in which the cross was made, the author states that while the  $F_1$  populations are as uniform as the parents, the  $F_2$  are nearly three times as variable as the  $F_1$  plants. Individuals reproducing *N. langsdorffii* were found in the  $F_2$  generation, certain of these  $F_2$  individuals reproducing their own form in the  $F_3$  generation. No  $F_2$  individuals reproducing *N. alata grandiflora* were found, but  $F_2$  plants approaching this type were produced. Galtonian regression occurred, but selected extremes regressed no more than those deviating moderately from the parental mean. Individuals from the same point on the  $F_2$  curve showed different variabilities in the  $F_2$  generation, such variations being always smaller than those of the  $F_2$  families.

The above conclusions, based upon corolla measurements, appear to be true also for other characters, except that in respect of such other characters, *N. alata grandiflora* types were reproduced. Corolla color and pollen color are said to show Mendelian inheritance, and this is considered to be the only logical interpretation of the other phenomena.

Linkage in *Primula sinensis*, E. ALTENBURG (*Genetics*, 1 (1916), No. 4, pp. 354-366).—The author claims to have found that crossovers between the pairs of linked factors long or short style and red or magenta flower, respectively, take place without reference to the crossovers between the pairs of linked factors red or magenta flower color and red stigma or green stigma, respectively; that is, there is no interference. Single anthers and single ovaries of the heterozygous individuals produce all classes of gametes. Reduction of factors must therefore accompany cell divisions occurring within many or all the anthers and ovaries. The proportions of the various gametic classes of linked factors are about the same for the anthers and the ovaries.

Some correlations in sugar beets, F. S. HARRIS and J. C. HOGENSON (*Genetics*, 1 (1916), No. 4, pp. 334-347).—This is a study of correlations in sugar beets between the several characters in order, if possible, to obtain short cuts in the process of improvement of desirable qualities. The tables given show correlations which, omitting decimal variations, may be expressed as follows: Weight of beet with percentage of sugar,  $-0.2878$ ; percentage of sugar in the mother beet with quantity of seed produced,  $0.0049$ ; height of plants with weight of seed produced,  $0.3985$ ; weight of the mother plant with quantity of seed

produced, 0.3075; number of stems on each plant with the quantity of seed produced, 0.2771; number of days to mature with quantity of seed produced, 0.1954; number of leaves on each stalk with quantity of seed produced, 0.1217; days to mature with height of plant, 0.1748; percentage of sucrose in the mother beet with days to mature seed,  $-0.1292$ ; and percentage of sucrose in the mother beet with number of leaves on each stalk, 0.2484.

What is happening to the hawthorns? L. M. STANDISH (*Jour. Heredity*, 7 (1916), No. 6, pp. 266-279, figs. 11).—Summarizing the results obtained from a study of *Cratægus* and from a review of contributions thereon, the author notes the facts that among the members of this genus a remarkable amount of comparatively recent multiplication of forms has become evident in the descriptive literature and that the presence of large numbers of local species in a given area is correlated with unusual sterility. Out of 171 specimens examined, only 35 could be regarded as being uncontaminated with regard to pollen conditions, while 76 showed from 50 to 100 per cent abortive grains. A study of other groups available is said to show parallel conditions, the pollen being usually good in the more widely distributed species but largely abortive in those of restricted areas.

The study of the genus *Cratægus* is said to give evidence of both systematic and morphological character which is considered to indicate the widespread occurrence of hybridism. The author concludes that among the members of this genus, at least, extreme variability is linked with extensive hybridism and the consequent multiplication of species rather than with mutation and the problem of the saltatory origin of species.

Influence of the composition and concentration of the nutrient solution on plants grown in sand cultures, A. H. AYRES (*Univ. Cal. Pubs. Agr. Sci.*, 1 (1917), No. 11, pp. 341-394, pls. 11, figs. 10).—The results are given of a series of tests with a hybrid species of *Nicotiana*, the plants being grown in washed sand and supplied with nutrient solutions containing sodium nitrate, calcium phosphate, potassium sulphate, and magnesium sulphate. The salts were so used as to give information regarding the separate compounds, the total concentration of salts, and the balance of salts in the solution, the height, leaf length, leaf width, flower production, and dry weight of tops being taken as indications of the influence of the solution on the growth of the plant.

Nitrogen was found a more important growth-limiting factor than phosphorus, while phosphorus, in turn, was more important than potassium. Plants grown in solutions of low concentration were in general superior to those grown in solutions of higher concentration. The author claims that the physiological balance of salts in the solution is an important factor which must be taken into consideration in connection with the composition and concentration of the solution, as growth is influenced by a combination of all these factors. The concentration of the nutrient solution was found to affect the economical use of nitrogen. Less calcium was absorbed from solutions at low concentrations than from those that had a high total concentration, but it seems to be used with greater economy in low concentrations than in high ones.

A comparative study of nutritive solutions in sand and water cultures, A. A. STOL'GANE (STOLHANE) (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, *Moskov. Sel'sk. Khoz. Inst.*, 10 (1914), pp. 289-336).—Experiments are reported in which a test was made of the comparative value of nutritive solutions prepared according to the formulas of Hellriegel, Crone, and Prianishnikov. From a study of barley and flax, the growth of plants and the absorption of nitrogen, phosphoric acid, sulphur, potash, and calcium was determined for the different solutions. Analyses are given of different parts of plants in the various cultures, from which it appears that the different

nutrient solutions produced varying results for the different species grown in both sand and water cultures. The rapidity of the absorption of the different compounds varied with the different plants, and an excess in the solution of any given material was not shown in its increased accumulation in the plants. The quantities of the various elements absorbed and assimilated were not always the same.

The effect of repeated growing of plants in nutritive solutions, E. A. ZHEMCHUZHNIKOV (GEMTCHOUGENIKOV) (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 327-354, pl. 1, figs. 3*).—Experiments are reported with a number of species of plants reseeded in sand cultures in which the same species had been previously grown.

The results showed that the growth was inversely proportional to the alkalinity of the solutions resulting from growing the previous crops. Where the nutrient solutions contained nitrates such as are recommended by Hellriegel, Knop, Crone, and others, the alkalinity was more pronounced and the growth more rapidly diminished than where ammonium nitrate was employed as a source of nitrogen.

The influence of the alkalinity of a solution on the transformation of nitrogenous material in germinating peas, V. A. MOROZOV (MOROSOV) (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 384-389, fig. 1*).—The author claims that the alkalinity of the nutrient solution retards the transformation of nitrogenous materials contained in seeds without changing the process.

The significance of the potassium ion in the synthesis of nitrogen compounds in the plant cell, J. STOKLASA (*Biochem. Ztschr., 73 (1916), No. 1-2, pp. 107-160*).—In continuance of previous work (E. S. R., 25, p. 125), the author has studied the rôle of potassium ions in the synthesis of nitrogen compounds, employing the sugar beet as well as bacterial cultures for this purpose.

It is thought that the potassium ion is concerned in the formation of nitrogenous materials in the bacterial cell, probably being connected with condensation and catalytic processes. In case of beets kept under illumination in an atmosphere free from carbon dioxid and supplied with carbon in the form of glucose, fructose, or saccharose, nitrogen compounds are formed by them both in the presence and in the absence of potassium ions. When the supply of plastic organic compounds in the cell is abundant, and there is solar illumination, nitrogen compounds may form without the presence of potassium, and they may form without sunlight in the presence of abundant potassium, carbon sources, and inorganic nutrients in the cell. Without potassium and in darkness, nitrogen compounds are not synthesized, even when the carbohydrates are abundant in available form. On complete exclusion of light, the potassium ion appears to serve as a source of energy and to condition the formation of carbohydrates through the action of respiratory enzymes. The processes of formation of new living cells and of dissimilation appear to be related in some way. Potassium is thought to play an important part in dissimilation and in physiological combustion and, in connection with light, to bring about catalytic reactions and photodynamic effects.

The rôle of calcium carbonate in the assimilation of ammonia, V. A. MOROZOV (MOROSOV) (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 390-395*).—The author has studied the effect of replacing calcium carbonate by ferric hydroxid. He has found that if the etiolated plants received ammonium sulphate as a source of nitrogen, the results were favorable to the addition of ferric hydroxid, but the action of calcium carbonate was more energetic.

The rôle of ammonia in the transformation of nitrogenous material in plants, D. N. PRIĀNISHNIKOV (PRIANICHNIKOV) (*Iz Rezult. Veget. Opytov. Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), Sup. 3, pp. 24*).—According to the author, plants may be divided into three groups, depending upon their utilization of ammonia. The first group, which is typified by maize, barley, pumpkin, etc., is readily supported by weak solutions of ammonium chlorid or ammonium sulphate, from which ammonia is readily absorbed and asparagin or glutenin formed.

The second group of plants absorbs ammonia feebly or not at all. However, on the addition of calcium carbonate, they take up ammonia rapidly and form asparagin. Peas and vetches are given as typical of this group.

In the last group, which is represented by *Lupinus luteus*, the introduction of ammoniacal salts into the solutions produces a profound change with the production of ammonia arising from the nitrogenous materials in the seeds. The addition of calcium carbonate does not reestablish the normal course of nitrogen transformation. The author attempts to explain, from his own or others' experiments, this unusual behavior of the lupine toward ammonium salts.

The formation of asparagin by *Lupinus luteus*, A. G. NIKOLAEVA (NICOLAEVA) (*Iz Rezult. Veget. Opytov. Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 380-383*).—Experiments are described which showed that etiolated plants of *L. luteus* behaved quite differently when ammonium nitrate, ammonium phosphate, and urea were present in the solutions from these plants when physiologically acid salts such as ammonium chlorid and ammonium sulphate were present. In the first case, there was an active formation of asparagin in proportion to the amount of ammonia absorbed, while in the second case ammonia accumulated in the plants without giving rise to the production of asparagin. Under the latter conditions, the phenomena of ammonia poisoning of plants were apparent.

The fixation of free nitrogen by certain fungi, C. O. CHAMBERS (*Plant World, 19 (1916), No. 7, pp. 175-194, fig. 1*).—Reporting studies by means of what is designated as the Folin method with *Aspergillus niger* and *Penicillium glaucum*, the author states that these fungi did not apparently make use of free nitrogen. This method is said to be very well adapted to work with very small quantities of material and to the determination of very small amounts of nitrogen.

A new case of symbiosis between a bacillus and a plant, P. GEORGEVITCH (*Roy. Bot. Gard. Kiev. Bul. Misc. Inform., No. 4 (1916), pp. 105, 106, figs. 21*).—In a preliminary note is described a case of symbiosis between a bacillus and *Kraussia floribunda* cultivated in the Kew Gardens. A description is given of the development, including spore formation, when transferred from nodules to potato or potato agar.

The assimilation of carbon dioxid, R. WILLSTÄTTER and A. STOLL (*Ber. Deut. Chem. Gesell., 48 (1915), No. 13, pp. 1540-1564; abs. in Jour. Chem. Soc. [London], 110 (1916), No. 639, I, pp. 105, 106*).—In a preliminary study of carbon dioxid assimilation, the authors found that the relation of chlorophyll content to assimilatory activity is variable. The most marked cases in this respect are those of leaves which are green in autumn, in which the assimilatory rate is relatively low, those of yellow varieties poor in chlorophyll, and those recovering color after etiolation and possessing a high assimilatory capacity.

A diminution in assimilatory activity as compared with chlorophyll content is observable during spring growth, and a comparable difference exists between young and old leaves. These differences are ascribed to a factor supposedly enzymatic in character. Leaves rich in chlorophyll show an assimilatory rate almost independent of the degree of illumination, the influence of the chlorophyll

factor then overcoming that of the enzym. Rise of temperature increases markedly the rate of assimilation in such leaves, while in leaves poor in chlorophyll that process is but little increased between 15 and 30° C., the enzym supposedly exerting its full effect in that case. The enzym, it is thought, may facilitate the decomposition of an intermediate compound of chlorophyll and carbon dioxide with liberation of oxygen.

Studies on the chemical transformations in the leaf of *Diospyros kaki* during the vegetative period and on its autumnal coloration, A. PARROZZANI (*Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale*, 3 (1915), pp. 43-90).—Concluding this partial report of a study of *D. kaki* as herein detailed, the author states that the facts as noted do not corroborate the view of a return of certain substances to the trunk before the fall of the leaves, but rather favor the view that the diminution of certain substances in the leaf at that time is caused by the action of water on the leaf and that the diminution of such substances as hydrocarbons may be attributed to oxidation. The autumnal red in leaves is thought to be due to the formation of a substance of glucosid nature which is altered in consequence of hydrolysis following oxidation.

On the assimilation of iron by plants, M. I. SIDORIN (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 241-257, pl. 1, figs. 5).—Investigations carried on in sand and water cultures in 1914, but not published until 1916, are held to show that the occurrence of chlorosis in plants grown in nutrient solutions with an excess of carbonates, especially calcium carbonate, depends on the alkalinity of the solution.

Alkalinity of itself is not the cause of chlorosis, but it is due to inaccessibility or lack of assimilation of iron under alkaline conditions. The same results may occur in nutrient solutions under conditions of physiological alkalinity. The ability of iron to form nearly insoluble compounds with phosphoric acid is often the cause of the poor assimilation of iron. The lack of chlorophyll in plants that have been grown without injury is partly analogous to chlorosis due to the lack of iron. It is claimed that iron has the property of being strictly localized in plant tissues, and this was conclusively shown in experiments with maize, in which the roots of plants were divided and grown in different solutions, one containing, the other lacking, iron.

Changes in the specific gravity of starches and dry substance of potatoes during the resting period, L. SZÉLL (*Kísérl. Közlem.*, 18 (1915), No. 5-6, pp. 1020-1029).—A study was made of two potato varieties kept in the cellar and also in heaps in the open air. It was found that the specific gravity of starches and dry substance increased in the potatoes kept in the cellar but not in those kept in the open. The conclusion is reached that it pays to winter potatoes in good, airy cellars.

Changes in the chemical composition of rye under the influence of species of *Fusarium*, A. ПОМАСКИЙ (*Soobshch. Būro Chastn. Rast.*, [Petrograd], 3 (1916), No. 1, pp. 32).—Analyses and experiments made with *F. roseum* and *F. subulatum* showed that their presence on rye caused a decrease in dry substance, chiefly starch and proteids, the percentage of which fell in ten days to 67.3 per cent and in two months to 25.1 per cent. The amount of starch decomposed in one month was from 61 to 80 per cent, in two months, 86.5 to 89.5 per cent. The total quantity of nitrogen in cultures of *F. roseum* decreased about 5 per cent in the first ten days, and in a month the amount of nitrogen in a culture of *F. subulatum* had diminished by 2.7 per cent. The decrease of nitrogen with both species amounted to from 12 to 16 per cent in two months. Both species of *Fusarium* were found to be able to decompose starch and protein. The products of the decomposition of protein were albu-

mose, peptones, amino acids, organic bases, ammonia, and a toxin, probably a nitrogenous glucosid. Other changes were noted in pentosans, sugars, cellulose, and fat.

## FIELD CROPS.

**Yields of spring grains in Illinois, W. L. BURLISON and O. M. ALLYN** (*Illinois Sta. Bul. 195 (1917), pp. 499-508*).—This bulletin reports variety tests with spring oats, spring wheat, spring barley, spring rye, and spring emmer conducted in the northern, central, and southern sections of Illinois. Data are presented in tabular form and discussed, and the leading oat varieties for each section noted. The tests with the other spring grains in northern Illinois have been too limited to draw definite conclusions. In central Illinois spring barley has given good results, but spring wheat is not deemed likely to become important unless the fall-sown wheat crop winterkills. The small spring grains (with the exception of early oat varieties) are not found well adapted to southern Illinois conditions.

Northern grown seed oats were not found to be sufficiently superior to home grown oats to justify their extra expense.

Characteristics of 31 oat varieties tested at DeKalb, Urbana, and Fairfield are given in tabular form as to maturity, color of kernel, foliage, form of head, and height.

**Grain drying, BERNSTEIN** (*Illus. Landw. Ztg., 36 (1916), Nos. 5, pp. 27-29, figs. 6; 6, pp. 34, 35, figs. 2*).—This article describes in detail several pieces of apparatus devised for the purpose of drying grain on a commercial scale. The construction of the various pieces is discussed and illustrated, and the cost of each piece estimated.

**Grading and baling Philippine fibers, H. T. EDWARDS** (*Philippine Agr. Rev. [English Ed.], 9 (1916), No. 1, pp. 5-12, figs. 2*).—The text is given of General Order No. 47, issued by the Government of the Philippine Islands, regulating the grading and handling of fiber crops in the Philippines. The regulations cover three main subjects, (1) designation of the official standard grades for each fiber, (2) determination of the standard grades and types thereof, and (3) additional regulations regarding baling, labeling, and inspection.

**One year of the fiber-grading law, M. M. SALEEBY** (*Philippine Agr. Rev. [English Ed.], 9 (1916), No. 1, pp. 13-20, pls. 2*).—This article discusses the operation of the fiber-grading law noted above.

It is pointed out that by the establishment of standard grades the Government has greatly facilitated the buying and selling of fiber. The educational work among the producers, instructing them in the proper methods of cleaning and handling the fiber, has aided materially in some districts. The distribution of literature pertaining to fiber grading among the commercial houses and the sending out of samples of the standard grades has also proved of great value.

**Description of the standard grades of Philippine fibers, M. M. SALEEBY** (*Philippine Agr. Rev. [English Ed.], 9 (1916), No. 1, pp. 21-30*).—This is a technical description of the standard grades of Philippine fibers as recognized by law.

The standard grades of abacá (Manila hemp) have been classified into four groups, according to the extent of the cleaning, as follows: (1) Those of excellent cleaning, grades streaky No. 3, streaky No. 2, streaky No. 1, midway, good current, superior current, and prime and extra prime; (2) those of good cleaning, grades brown, seconds, and current; (3) those of fair cleaning, grades medium, fair, and good fair; and (4) those of coarse cleaning, grades coarse brown, coarse, and daet. The standard grades of maguey and sisal are grouped

as (1) retted fiber, grades maguey or sisal No. 3, maguey or sisal No. 2, and maguey or sisal No. 1; and (2) knife or machine cleaned fiber, grades maguey or sisal, common, fair, and good.

**Fiber-grading stations and grading establishments, M. M. SALEEBY** (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 1, pp. 42-47).—This is a list of the regularly authorized fiber-grading stations in the Philippine Islands.

**Statistical report of fiber production in the Philippine Islands during the year 1915, M. M. SALEEBY** (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 1, pp. 31-41, pls. 3).—This is a detailed report of fiber production in the Philippines for 1915, showing a grand total of 1,071,983 bales for the year. The production in bales is also given for each province.

**The important legumes.—I, Peas, vetches, field beans, lupine, and lentil, C. FRUWIRTH** (*Landw. Hefte, No. 29 (1916), pp. 42, figs. 9*).—This publication discusses in a popular manner the value of leguminous plants in agriculture. Several specific crops are described and their value, both for human use and for agricultural purposes, discussed. The following varieties are described in detail, together with mention of common local varieties: (1) Peas (*Pisum sativum* and *P. arvense*); (2) field beans (*Vicia faba*); (3) yellow lupine (*Lupinus luteus*) and the narrow-leaved lupine (*L. angustifolius*); (4) vetch (*V. sativa*); and (5) lentil (*Lens esculenta*).

A device for sorting peas is described and illustrated.

A method for removing the bitter flavor of lupines is described and an apparatus for that purpose illustrated.

**Why alfalfa sometimes fails in Iowa, O. F. JENSEN** (*Iowa Agr.*, 17 (1916), No. 2, pp. 57-60, fig. 1).—This article gives the results of an investigation of 1,300 reports from alfalfa growers in 75 counties of the State of Iowa. The complete failures reported numbered 247, or one out of every six seedings. An analysis of 197 of these failures indicated that the causes were as follows: Lack of inoculation, or lack of lime, or both, 79; smothered by nurse crop, 27; smothered by weeds, 22; winter killed, 18; poor preparation of seed bed, 16; drilled or covered too deep, 12; poor soil, lack of fertility, 8; drought, 5; poor drainage, 4; rains washed out, 4; and poor seed, 2.

**Flax culture in South Dakota, A. N. HUME, M. CHAMPLIN, and J. MARTIN** (*South Dakota Sta. Bul. 169 (1916), pp. 466-493, figs. 11*).—This bulletin is a general discussion of flax culture in an effort to revive interest in flax production in South Dakota. Variety tests, date- and rate-of-seeding tests, and rotation tests have been conducted at the Cottonwood, Eureka, and Highmore substations of the South Dakota Station, and in cooperation with the U. S. Department of Agriculture on the Belle Fourche Experiment Farm, Newell, S. Dak.

The flax commonly grown in South Dakota is of the small-seeded, blue-flowered European type, although the pedigreed varieties North Dakota Resistant No. 52 (S. D. 29) and Select Russian N. D. 1215 (S. D. 686) have yielded best in variety tests at Highmore and Newell, respectively. It is recommended that flax follow a pasture, meadow, or cultivated crop, and that the rotation extend over a long period. Several tests of rotation systems are in progress. Early seeding is recommended, April seedings of 2 pk. per acre being deemed preferable to late light seedings. Flax responds to irrigation, but overirrigation and too late irrigation must be avoided. General notes are given on the harvesting, threshing, and disposal of the crop.

**Some varieties of Indian gram (Cicer arietinum), A. and GABRIELLE L. C. HOWARD and A. RAHMAN KHAN** (*Mem. Dept. Agr. India, Bot. Ser.*, 7 (1915), No. 6, pp. 211-235, pls. 3, figs. 2).—This bulletin is a description of the varieties of gram (*C. arietinum*), the Indian cold-season food grain, together with a

discussion of the morphological and cultural characteristics of the plant. The area grown to gram every year is approximately 18,000,000 acres and the average yield is 688 lbs. per acre.

Extensive experiments have been conducted at Pusa to determine the cultural requirements of the crop. It has been determined that gram does best on the light soils, and that extensive aeration of the soil is imperative for its successful production. Packing the soil, heavy soils, and too high soil moisture content are limiting factors in gram production. The harmful effects do not appear until flowering time, when the plant will suddenly wilt and the production of an apparently vigorous crop fall off quite appreciably. In addition to these limiting soil factors, humidity and rainfall also act to limit production. High humidity at flowering time results in a greatly reduced setting of pods.

The gram plant is normally a self-fertilized plant, although natural cross-fertilization is known to occur. Several such crosses are reported as occurring at Pusa. The 25 types so far isolated at Pusa are classified, and a key arranged for their identification. Brief descriptive notes for each type are given. A great number of variations in color of blossom and seed are to be noted between the different types. Other striking differences are to be found in the habit of growth and in the root development. The quality of the seed increased as the color of the seed approaches the lighter shades.

A report of the cultural experiments of the German Potato Culture Station for 1915, C. VON ECKENBRECHER (*Ztschr. Spiritusindus.*, 1916, *Ergänzungsh.*, pp. 3-52).—This is a detailed report of the potato culture experiments conducted by this station at its outlying experiment fields for 1915. The plans of the experiments are given in detail, together with the tabulated results with 19 varieties at 32 experiment fields situated in 14 provinces. The meteorological conditions prevailing at each substation from April 1 to October 31 are given in tabular form and discussed, and the results of the experiments since 1892 are summarized for purposes of comparison.

The average yield of all varieties for 1915 showed an increase of 9.7 per cent over that of 1914, but the average starch content showed a decrease of 0.6 per cent. Some notes are also given on disease resistance of the tested varieties at the various substations.

Cuttings for the propagation of potatoes, L. KIESSLING (*Deut. Landw. Presse*, 43 (1916), No. 4, p. 25).—Some notes are given on the literature pertaining to the propagation of potatoes by the use of vegetative cuttings other than the tubers. Numerous tests with different varieties are cited showing the possibilities of high production from a small quantity of the mother stock. The use of potato seedlings for propagation work of this sort is also discussed.

Potato variety tests at Kloster Hadmersleben, F. HEINE (*Ztschr. Spiritusindus.*, 1916, *Ergänzungsh.*, pp. 53-61).—This is a report of variety tests with 14 early, 36 medium late, and 38 late varieties at the Kloster Hadmersleben experiment station for the year 1915. The meteorological conditions for the years 1912 to 1915 are given in tabular form, as well as the average production of the highest yielding varieties for the last five years, and a description of each variety.

Methods and aims in potato breeding, P. HOLDEFLEISS (*Illus. Landw. Ztg.*, 36 (1916), No. 17, pp. 106-109, figs. 17).—This article discusses in a general way the necessity and value of selection for improving the potato crop. A number of varieties are illustrated and brief descriptions given. It is recommended that some definite scheme for tabulating the characteristics of the varieties studied be adopted, and a plan for making such reports is submitted.

*Solanum commersonii*, the swamp potato, SIEBERT (*Illus. Landw. Ztg.*, 36 (1916), No. 17, pp. 110, 111, figs. 2).—A variety of tuber-bearing *Solanum* from South Australia is described and illustrated as *S. commersonii*. The cultural characteristics of the plant are described in detail. A number of experiments are cited, describing the gradual adaptation of the plant and its development into a product of economic value. The species is deemed especially noteworthy for its resistance to cold and disease.

Sudan grass, T. B. HUTCHESON, E. R. HODGSON, and T. K. WOLFE (*Virginia Sta. Bul.* 212 (1916), pp. 3-15, figs. 4).—This bulletin is a general discussion of Sudan grass (*Andropogon sorghum*), its adaptation to Virginia conditions, and its value as a forage crop. Date and rate-of-seeding tests, tests of seeding with cowpeas or soy beans, and seed production experiments conducted at Blacksburg are reported in tabular form and briefly discussed. Analyses of the cured hay of Sudan grass are quoted from Oklahoma (E. S. R., 32, p. 739) and Texas (E. S. R., 33, p. 41).

For hay, seedlings of from 30 to 40 lbs. per acre, broadcasted, are recommended as early as all danger of frost is over in the spring and not later than July 1. For seed production, seedlings of 20 lbs. per acre, sown in drills from 24 to 30 in. apart, are suggested. Sudan grass may be seeded with cowpeas or soy beans at the rate of 12 lbs. of grass seed to 1 bu. of peas or beans. It is important that the seed be free from Johnson grass, the seed of which it closely resembles.

A summary of the manurial experiments with sugar cane in the West Indies, W. R. DUNLOP (*West Indian Bul.*, 15 (1915), No. 3, pp. 212-234).—This article reports 25 years of experimental work with fertilizers on sugar cane in the West Indies. These experiments have been conducted in the Leeward Islands (Antigua and St. Kitts), Barbados, Trinidad, and British Guiana, and the results obtained and conclusions drawn at each place discussed in detail.

Plats of from 1/20 to 1/30 of an acre are recommended for sugar cane experiments. Notes are given on the precision of the West Indian methods, showing the number of plats necessary in fertilizer experiments with sugar cane for a desired percentage difference between average yields when the probable error of one experiment is 12, 15, or 20 per cent.

Sugar cane on the experimental fields.—Crops of 1914, J. B. HARRISON, C. K. BANCROFT, and R. WARD (*Jour. Bd. Agr. Brit. Guiana*, 9 (1916), No. 2, pp. 63-93).—A report of the sugar cane experiments in British Guiana for 1914.

Considerable space is devoted to a discussion of variety tests, including seedlings and hybrids. Several fertilizer experiments are reported. Nitrogenous fertilizers, especially ammonium sulphate, greatly increased the yield of cane, while phosphorous had very little, if any, effect on cane production. Several soil samples were analyzed mechanically and chemically in an effort to determine any changes that were taking place in the soil.

Sweet clover, T. S. PARSONS (*Wyoming Sta. Bul.* 110 (1916), pp. 3-15, figs. 4).—The adaptation of sweet clover to Wyoming conditions is discussed and its use recommended. *Melilotus alba* and *Medicago officinalis* have both been tested.

Cultural experiments indicate that sweet clover is especially valuable in Wyoming to prepare heavy, hard, and poor soils for alfalfa, that it will grow on land too wet or too dry for alfalfa, and that it is more resistant to alkali conditions than the latter. The plant is also adapted to growth under irrigation or under dry-farming conditions, and produces seed freely in either case.

Experiments are in progress to determine (1) the value of sweet clover as a fertilizer for the succeeding crops, and (2) its value in a complete crop rota-

tion, but only the methods of soil preparation, seeding, and yields are discussed at this time. The results indicate that sweet clover will not do so well on well-prepared soil as on that less thoroughly prepared, compactness of the soil seeming to be the essential factor. A yield of 2,930 lbs. of cured hay was secured from a half-acre plat sown to sweet clover after alfalfa and where deep plowing had been impossible, as compared with failure to obtain a stand from plats which had been seeded to grain the two preceding years.

Sulphuric acid treatment of sweet clover seed gave a total germination percentage of 89, as compared with 78 per cent for scarified seed and 48 per cent for untreated seed.

Sweet potato culture, T. C. JOHNSON and J. T. ROSA, JR. (*Virginia Truck Sta. Bul.* 19 (1916), pp. 387-415, figs. 13).—This bulletin deals with the cultivation and marketing of sweet potatoes in the eastern portions of Virginia.

The proportion of grain to straw in varieties of wheat, J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 4, pp. 229-231).—Some notes on tests with 55 varieties of wheat at the Cowra Experiment Farm for 1915 are given. The object of these experiments was to estimate the relative productiveness of the varieties and their suitability for hay.

Selection plats.—A reminder to wheat growers, J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 4, pp. 233, 234).—Directions are given to farmers for laying out seed plats for the purpose of selecting their own seed wheat.

[Seed corrosion and its prevention], E. MOLZ (*Landw. Wchnschr. Sachsen*, 18 (1916), No. 9, pp. 79-81).—This article deals with the treatment of wheat with formaldehyde and its effect on germination. Varying strengths of formaldehyde were used and the germination of the seed tested in artificial seed beds and in the field. The range of germination in the artificial seed bed was from 14.5 to 96.5 per cent, while in the field the range was from 0 to 85.6 per cent.

The seed situation in Utah, G. STEWART (*Utah Sta. Circ.* 23 (1916), pp. 3-31, figs. 12).—This circular is a general discussion of the selection and testing of seed for planting. Specific directions are given for the testing of cereals, grasses, vegetables and flowers, and potatoes, and for the field selection of seed of the small grains, corn, potatoes, and forage crops.

The seed business in the first year of the war, M. HEINRICH (*Illus. Landw. Ztg.*, 35 (1915), No. 104, pp. 669, 670).—This article gives a brief discussion of the German seed situation in respect to prices and the source of the seed for a number of the more common grasses and clovers.

Clover and grass seed for spring sowing, 1916, M. HEINRICH (*Illus. Landw. Ztg.*, 36 (1916), No. 15, pp. 91, 92).—This article discusses the average germination, purity, and cost of a number of the more common clover and grass seeds available for sowing in 1916 as compared with the averages for the past 10-year period. The data are presented in tabular form.

[Computing actual values of clover and grass seed], M. HEINRICH (*Deut. Landw. Presse*, 43 (1916), No. 8, pp. 57, 58).—This article describes a method for computing the actual value of a grass or clover seed, based on the following formula:

$$x = \frac{(R+r) \times (K+k) \times a}{Rg \times Kg}$$
 In this formula,  $Rg$ =guaranteed purity of seed;  $Kg$ =guaranteed germination of seed;  $R$ =actual purity;  $K$ =actual germination;  $r$ =variation in purity;  $k$ =variation in germination; and  $a$ =stipulated price.

Characteristics of quack grass (*Agropyron repens*) and western wheat grass (*A. occidentale*), with special emphasis on the eradication of quack grass, A. N. HUME and S. L. SLOAN (*South Dakota Sta. Bul.* 170 (1916), pp. 497-524, figs. 9).—Quack grass and western wheat grass are described and compared and their habits of growth illustrated. Special emphasis is laid on

the eradication of quack grass, the following methods being recommended, according to local conditions: Hand digging; smothering with tarred paper or mulch; summer fallowing; and grazing or cutting for hay, followed by fallowing.

Observations of the results obtained by several farmers, using modifications of the summer fallow system, indicate that the best results are obtained from cultivation during July and August followed by a cultivated crop. The cost of this operation was estimated at \$15 per acre, and the fact is noted that a number of sheep could be purchased for that amount and grazed on the infested land to good advantage. Continued grazing weakens the root stock and brings it nearer the surface.

The root system of western wheat grass is not nearly so strong as that of quack grass, being unable to withstand thorough cultivation.

[The control of hedge mustard with finely powdered kainit], SCHNITZLER (*Illus. Landw. Ztg.*, 36 (1916), No. 14, pp. 83, 84).—This article is a discussion of the control of weeds by the use of powdered kainit applied in solution. A list of weeds is given, arranged in the order of their resistance to this treatment.

Two points are considered, the degree of influence of kainit on different weeds and why cereals are not injured by the use of kainit. Three reasons are advanced to show why different weeds are affected in varying degrees, (1) that plasmolysis varies in different plants due to protective structures, (2) that the hairy growth on certain plants serves as a mechanical protection, and (3) that the oily coating found on several plants furnishes a protection. The immunity of cereals is attributed to certain cultural characteristics, such as the arrangement of the leaves, upright habit of growth, and the high osmotic pressure developed in the cells of the plant.

Weeds of New South Wales, J. H. MAIDEN (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 4, pp. 247-253, pls. 2).—This is a popular and botanical description of two weeds of New South Wales, the cape weed (*Cryptostemma calendulacea*) and Hexham scent (*Melilotus parviflora*), including a brief discussion of cultural characteristics and methods of control.

## HORTICULTURE.

Johnson's gardeners' dictionary and cultural instructor, G. W. JOHNSON, edited by J. FRASER and A. HEMSLEY (*London: George Routledge & Sons, Ltd.* [1917], new ed., pp. 923).—The present edition of this old English work, although based on the original edition of 1846, has been thoroughly recast and brought down to the year 1917, both from the standpoint of plant nomenclature and cultural practices. Many thousand names of new plants have been added.

The complete gardener, H. H. THOMAS (*London and New York: Cassell & Co., Ltd.*, 1916, 4. ed., pp. XVI+579, pls. 128, figs. 72).—A manual of information relative to the more desirable hardy flowers, greenhouse flowers, evergreen and blossoming shrubs, fruits, and vegetables, including directions for their culture under glass and in the open.

Garden planting and planting, edited by H. H. THOMAS (*London and New York: Cassell & Co., Ltd.* [1915], pp. [VI]+150, pl. 1, figs. 138).—A popular treatise on the subject.

Gardening made easy, edited by E. T. COOK (*London: Country Life*, 1916, 6. ed., pp. 217, figs. 24).—A popular treatise on ornamental and vegetable gardening in the open and under glass, including also a chapter on fruit culture.

Kitchen and market gardening, L. BUSSARD (*Culture Potagère et Culture Maraîchère*. Paris: J. B. Baillière & Sons, 1916, 3. ed., rev. and enl., pp. 524,

*figs. 215*).—The present edition of the author's work (E. S. R., 15, p. 674), which is one of a series constituting the agricultural encyclopedia published under the direction of G. Wery, has been completely revised to include more recent knowledge relative to amateur and professional gardening practices.

[Overhead irrigation results in 1916], E. F. PALMER (*Agr. Gaz. Canada*, 4 (1917), No. 2, pp. 125-127, *fig. 1*).—Some data are given on tests of overhead irrigation conducted with raspberries and vegetables by the Ontario Horticultural Experiment Station, Vineland, in 1916. The results in brief indicate that overhead irrigation may be used with considerable profit during periods of drought.

Cucumber growing, C. P. HALLIGAN (*Michigan Sta. Circ. 30* (1916), pp. 4).—A revision of Circular 19 of the station previously noted (E. S. R., 29, p. 145).

Commercial onion growing, C. B. SAYRE (*Indiana Sta. Circ. 57* (1916), pp. 27, *figs. 12*).—This circular describes the most successful practice in the commercial production of onions on the muck lands of northern Indiana. The subject matter is based upon observations, correspondence, and special field studies conducted by the author in 1915 and 1916, supplemented by observations made by W. E. Lommel in 1915. In addition to details for growing, harvesting, and marketing the main onion crop, information is also given relative to the production of onion sets, onions for pickling, and onion seed, including directions for the control of insects and diseases.

The use of brine tank refrigerator cars for fruit shipments (*Agr. Gaz. Canada*, 4 (1917), No. 2, pp. 110-114, *figs. 8*).—A summarized account of experiments conducted with the brine tank refrigerator car by the Dominion Department of Agriculture during the season of 1916. With the use of 5 per cent salt and crushed ice in conjunction with slatted floor racks a good brine tank car has given very much more satisfactory results than a poor block ice car.

The relation of fruit growing to soil fertility, R. C. THOMPSON (*Arkansas Sta. Bul. 123* [*tech. ed.*] (1916), pp. 3-20).—A technical edition of the bulletin previously noted (E. S. R., 36, p. 39).

The Indiana farm orchard operating costs and methods, C. G. WOODBURY, M. W. RICHARDS, and H. J. REED (*Indiana Sta. Bul. 194* (1916), pp. 3-79, *figs. 56*).—This bulletin discusses the conditions of success in the renovation and operation of farm orchards, outlines the conditions underlying successful fruit growing in such a way as to enable orchard owners to form a correct judgment in regard to their own opportunities, and presents figures on operation costs in several farm orchards as summarized from records compiled during the last five years.

The data on operation costs were secured from eight orchards located in several fruit-growing districts of the State and ranging in size from 4 to 30 acres. The cost of the various operations are given in detail in most cases for each season and averaged for the 5-year period, both for the individual orchards and the orchards as a whole. Summarizing the data as a whole for all of the orchards during the 5-year period the total management cost was \$1.37 per tree, \$56.68 per acre, 44.7 cts. per bushel, and \$1.35 per barrel. The average yield per acre was 232.4 bu.

On the cause of alternate bearing in the apple, O. BUTLER (*Bul. Torrey Bot. Club*, 44 (1917), No. 2, pp. 85-96, *pls. 3, fig. 1*).—After reviewing the investigations conducted at the New Hampshire Experiment Station, as well as at other state stations and abroad, the author concludes that to obtain regular fruitfulness in apple trees of bearing age the yearly departures from the mean growth must be small. Pruning may be considered as the most potent means of regularizing bearing; in fact, the only really effective means of accomplishing this object.

The identification and classification of pears, G. LUIZET (*Jour. Soc. Nat. Hort. France*, 4. ser., 17 (1916), May, pp. 74-78; *abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 8, pp. 1119, 1120).—An outline is here given of a scheme for identifying and classifying pears that has recently been worked out by L. Chasset and is to be published in full at a later date.

Origin and development of hardy, blight-resisting pears, C. G. PATTEN (*Minn. Hort.*, 45 (1917), No. 3, pp. 97-102, pl. 1, figs. 2).—A popular review of the work of the author and other investigators in the attempt to secure hardy, blight-resisting pears for culture in the United States.

The cherry and its industrial culture, A. A. HINZENBURG (*Vishnu i eñ Promyshlennaiñ Kultura. Petrograd: Imp. Ross. Obshch. Plod.*, pts. 1 (1914), pp. 108, figs. 48; 2 (1915), pp. 111, figs. 65).—Part 1 of this work deals with the description and classification of cherries, together with various cultural operations. Part 2 takes up the diseases and pests of cherry trees and methods of control. The methods of harvesting and packing cherries and the preparation of various cherry products are also considered.

Variations of a sexual hybrid of the vine by grafting it on one of its procreators, F. BACO (*Compt. Rend. Acad. Sci. [Paris]*, 163 (1916), No. 23, pp. 712-714).—In continuation of previous studies on variations in grafted grapevines (E. S. R., 29, p. 148), the author here reports a case in which a hybrid when used as a scion changed its mosaic and general appearance and assumed latent characters of the stock and of one of its maternal ancestors.

The hybrid direct bearers in the valley of the Rhone in 1916, A. DESMOULINS and V. VILLARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 38 (1917), Nos. 2, pp. 36-42; 3, pp. 59-62).—In continuation of previous data (E. S. R., 35, p. 41), observations are given for the seventeenth year relative to the behavior of a large number of hybrid direct-bearing grapes, with special reference to their resistance to disease, adaptation to various soil conditions, and relative time of budding.

Blueberry culture, ELIZABETH C. WHITE (*Woman's Nat. Farm and Gard. Assoc.*, 3 (1917), No. 3, pp. 3-10).—The author describes in detail methods employed in preparing a piece of swamp land for blueberry culture and in the propagation and planting of selected wild blueberries. The work was conducted at Whitesbog, N. J., in cooperation with the U. S. Department of Agriculture (E. S. R., 35, p. 647).

Fertilizer experiments with cranberries in 1916, F. P. SCHLATTER (*Proc. Amer. Cranberry Growers' Assoc.*, 47 (1917), pp. 13-16).—A summary of results secured in 1916 in cooperative experiments being conducted under the direction of the New Jersey Experiment Stations (E. S. R., 34, p. 834).

The results of the work thus far secured indicate that sandy bogs respond favorably to fertilizer treatment, but that it is unwise to apply fertilizers in any great amount to muck bottom bogs, with the possible exception of those fertilizers carrying phosphorus.

The continued increased yield in sandy land in 1916 is attributed to the residual effect of fertilizer, since none of the plats were fertilized since 1915.

Progress in vegetative propagation of tropical fruits, P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 3, pp. 257, 258).—The author gives brief directions for the propagation of a number of species of tropical fruits. The directions are based upon work conducted at the Lamao Experiment Station.

History of the avocado and its varieties in California with a check list of all named varieties, I. J. CONDIT (*Mo. Bul. Com. Hort. Cal.*, 6 (1917), No. 1, pp. 1-21, figs. 5).—In addition to brief historical notes on the avocado in

California, 54 varieties originating in the State and 86 varieties originating elsewhere are here listed.

The cultivation and fertilization of the avocado in Florida, W. J. KROME (*Cal. Citrogr.*, 2 (1917), No. 4, pp. 12, 21, 22, fig. 1).—The author's methods of cultivating and fertilizing avocado trees as experimentally developed during the past few years are here described.

Inherent characteristics of *Theobroma cacao*, and a summary on cacao experiments, F. E. OLIVIERI (*Proc. Agr. Soc. Trinidad and Tobago*, 16 (1916), No. 12, pp. 461-474).—A description of the inherent characteristics of the cacao tree, together with a brief summary of some of the more important investigations dealing with cacao.

Note on the species and varieties of coffee grown in Java, P. J. WESTER, trans. by H. MAUBY (*Bul. Econ. Indochine, n. ser.*, 19 (1916), No. 121, pp. 624-637).—A French translation of the author's article previously noted (E. S. R., 35, p. 745).

The cultivation of guavas in Gujarat, L. B. KULKARNI (*Dept. Agr. Bombay Bul.* 79 (1916), pp. 14, pls. 3).—An account of native methods of growing guavas in different sections of Gujarat, including analyses of soil and fruit, estimated data on the cost of growing guavas, and brief suggestions relative to improvement in cultural methods.

Effect of fertilizers on the composition and quality of oranges, H. D. YOUNG (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 4, pp. 127-138).—In connection with a continuous fertilizer experiment started by the California Experiment Station in 1907, and which has been reported on from time to time (E. S. R., 36, p. 138), a study was undertaken in 1914 and 1915 relative to the effect of the various fertilizers on the quality and composition of oranges. Analytical data are given and discussed both for Valencia and navel oranges fertilized differently, for oranges grown on light and heavy soil, and fertilized with commercial fertilizer and with organic matter. Other investigations along similar lines are briefly reviewed.

Nitrogen was the only element which seemed to exercise a specific effect on the composition of the oranges. No great differences in composition were observed between oranges fertilized with commercial fertilizer and with organic matter. Likewise, oranges grown on a light soil and a heavy soil did not show material difference in composition under the same fertilizer treatment. Applications of nitrogen to the soil resulted in a slightly lower amount of sugar, a somewhat coarser fruit, and a little less juice in the orange, regardless of whether the nitrogen was in combination with either potash or phosphoric acid, or both. The effects of nitrogenous fertilizers were greater in the 1915 crops, which were harvested about two months later than the 1914 crops, thus indicating that nitrogen produced an effect other than that of merely delaying the time of maturity. A comparison with fruit from similar trees grown outside the fertilizer plats showed a fair agreement of composition and quality. The analyses show a higher percentage of nitrogen from all plats receiving it, while no such effect was obtained with either phosphoric acid or potash.

Notes on medicinal plants, A. HOSKING (*West of Scot. Agr. Col. Bul.* 78 (1917), pp. 99-149).—This bulletin discusses the possibilities and limitations of the cultivation and collection from wild sources of medicinal plants in Scotland, gives directions for growing herbs, and presents a list of hardy herbs, trees, and shrubs used in medicine.

Collection, drying, and cultivation of medicinal plants in Russia, V. L. KOMAROV (*Sbor, Sushka i Razvedenie Lekarstvennykh Rastenii v Rossii. Petrograd: Dept. Zeml.*, 1916, 2. ed., pp. 128, pls. 66).—A manual of information relative to the collection, drying, and cultivation of medicinal plants, including

descriptive lists of plants adapted for culture in different parts of Russia and reports from experimental cultures undertaken as a result of the distribution of seeds and plants in different parts of the country.

Notes on cinchona in Java, P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 4, pp. 273-277, pls. 3).—A brief account of methods employed in growing cinchona in Java, based on a report made by the author in 1915 after a visit to Java.

Bulb growing for amateurs, H. H. THOMAS (*London and New York: Cassell & Co., Ltd., 1915, pp. VIII+151, figs. 148*).—A popular treatise on bulb culture under glass and in the open, with suggestions relative to varieties adapted to different seasons and situations.

Gladiolus studies.—I, Botany, history, and evolution of the gladiolus, A. C. BEAL (*N. Y. State Col. Agr., Cornell Univ., Ext. Bul. 9 (1916), pp. 93-188, pl. 1, figs. 7*).—This is the first contribution on gladiolus studies undertaken by the department of horticulture in 1910 and later continued by the department of floriculture of Cornell University in cooperation with the American Gladiolus Society.

The present bulletin traces the development of the gladiolus up to the present time. The subject matter is discussed under the following headings: Botany of the gladiolus; history of the genus; evolution of the gladiolus, including history of garden species, hybrid gladioli, and history of gladiolus in America; and bibliography of the gladiolus, including botanical works, special works, references to history and development, color plates and figures of gladiolus species, hybrid gladioli, and horticultural varieties.

Gladiolus studies.—II, Culture and hybridization of the gladiolus, A. C. HORTES (*N. Y. State Col. Agr., Cornell Univ., Ext. Bul. 10 (1916), pp. 189-271, pl. 1, figs. 29*).—In continuation of the above, the present bulletin discusses the culture and hybridization of gladiolus, the subject matter being based on four years' observations made at the trial grounds of the American Gladiolus Society at Cornell University, on conversations and correspondence with many gladiolus experts, and on a review of the literature of the subject.

The following phases are discussed: The gladiolus as a cut flower and as a garden subject; soils for the gladiolus; fertilizers and their use; time and manner of planting; spring and summer culture; the gladiolus bloom; ideals in flower and in growth; hybrids and hybridization, including a general discussion, crossing technique, and suggested improvements; gathering and planting seeds; methods of propagation; indoor culture; insect and animal pests; and gladiolus diseases. An extensive bibliography of related literature is appended.

A report on varieties tested at Cornell University will be issued at a later date.

Field notes on sweet peas, edited by L. L. MORSE (*San Francisco, Cal.: C. C. Morse & Co. [1916], rev. ed., pp. 220, figs. 12*).—The present edition of this work includes 1,870 varietal names of sweet peas that have been listed either in American, British, or Australian publications. Historical notes are given on the various classes and types, the varieties are listed according to color and preference, and the varieties are then described with reference to the introducer, year of introduction, color and character of bloom, and similar varieties. Notes are also given on Mendelism in sweet peas, culture, and insect troubles.

Everybody's flower garden, H. H. THOMAS (*London and New York: Cassell & Co., Ltd., 1916, pp. VII+152, figs. 118*).—A popular treatise on ornamental gardening, including information relative to the development of various types of gardens and plants adapted for each.

Studies in gardening, A. CLUTTON-BROCK (*New York: Charles Scribner's Sons, 1916, pp. XX XVIII+337*).—An American edition of the author's work, edited and annotated by Louisa Y. King. The work as a whole comprises a collection of some 30 articles upon both the theory and practice of ornamental gardening that originally appeared in the form of letters in the *London Times*.

Garden ornaments, MARY H. NORTHEM (*New York: Duffield & Co., 1916, pp. [XI]+178, pls. 32*).—A popular work dealing with the treatment of the garden path and border, steps, entrances, seats, and other garden accessories, such as the pergola and arch, bird baths, pools, sundials, fountains, etc.

## FORESTRY.

Some public and economic aspects of the lumber industry.—Studies of the lumber industry, I, W. B. GREELEY (*U. S. Dept. Agr. Rpt. 114 (1917), pp. 100, pls. 3, figs. 14*).—This comprises the first report on a study of the conditions in the timber-using industries conducted by the Forest Service in cooperation with the Bureau of Corporations and later with the Federal Trade Commission. The investigation as a whole was conducted to obtain the facts necessary to an understanding of the lumber industry and the further development of a public forest policy.

The present report presents a general view of the whole investigation under the following general headings: The industrial side of forest conservation, present conditions in the lumber industry, why the lumber industry is unstable, how the public is concerned, what the situation calls for, the use of public timber, and a public forest policy. Detailed studies are to be presented in subsequent publications.

The essentials of American timber law, J. P. KINNEY (*New York: John Wiley & Sons, Inc., 1917, pp. XXI+279+X*).—A presentation of the existing laws regarding trees and their products as property, with certain observations and references to historical development deemed necessary to an understanding of the reasons for existing laws. The general interpretation of the laws is accompanied in each case by page citations to the compiled laws of the different States on the subject.

Instructions for the scaling and measurement of National Forest timber (*U. S. Dept. Agr., Forest Serv., 1916, pp. 94*).—The instructions contained in this pamphlet are supplementary to the National Forest Manual (E. S. R., 26, p. 340) and are intended for use in the administration of timber sales, timber settlements, timber trespass, free use, and other administrative use.

Historical review of Canada's timber industry, J. LAWLER (*Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1227-1234*).—The author sketches the genesis and development of timber regulations in Canada since the French régime.

The forest trees of Canada, R. G. LEWIS (*Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1234-1241*).—A list is given of the coniferous and deciduous tree species of Canada, including brief notes on some of the more important timber species.

Commercial woods of the Philippines: Their preparation and uses, E. E. SCHNEIDER ([*Philippine*] *Bur. Forestry Bul. 14 (1916), pp. 274, pls. 10, figs. 12*).—This bulletin replaces Bulletin 11 of the Bureau of Forestry (E. S. R., 28, p. 439). The scope of the work has been considerably extended by the addition of much new material and related material gathered from various publications. The principal works consulted are here listed.

The subject matter is discussed under the headings of forests, timber supply, markets; properties of wood, methods of conversion, working and finishing,

preservative treatment; uses; methods of identification; and species descriptions. Data on the mechanical properties of 34 Philippine woods, shipping weights, grading rules, and lists of woods based on the durability of sapwood are appended.

The trees of North Carolina, W. C. COKER and H. R. TOTTEN (*Chapel Hill, N. C.: W. C. Coker, 1916, pp. 106*).—This work contains popular descriptions of the trees of North Carolina, including a key for the identification of the species.

Western yellow pine in Oregon, T. T. MUNGER (*U. S. Dept. Agr. Bul. 418 (1917), pp. 48, pls. 7*).—An account of the western yellow pine in Oregon, discussing its distribution and abundance, distinguishing characteristics, climatic and soil requirements, reproduction, effects of fire, sources of injury other than fire, character of the stands, growth, characteristics of the wood, utilization of yellow pine forests, logging and milling, planting, and management. Volume tables for western yellow pine, instructions for marking timber in the yellow pine region, and instructions for brush burning under the selection system of cutting are appended.

Hybrids and other new chestnuts for blight districts, W. VAN FLEET (*North. Nut Growers Assoc. Proc., 7 (1916), pp. 54-58*).—A paper on this subject read before the annual meeting of the Northern Nut Growers' Association, Washington, D. C., in September, 1916.

Fourth biennial report of the state forester, J. C. VAN HOOK (*Bien. Rpt. State Forester, Mont., 4 (1915-16), pp. 55, pl. 1, figs. 15*).—A report of activities during the fiscal years 1915 and 1916, including information relative to timber resources and timber industries of the State, qualities and uses of the more important Montana woods, progress in wood preservation, fire protection, instructions for farm and city tree planting, and brief descriptions of some of the mountain forests of Montana as places for recreation.

Report of the state forester to the State Board of Forest Commissioners for the period ended November 30, 1914, E. W. FERRIS (*Ann. Rpts. Wash. State Forester, 1913-14, pp. 29*).—This report deals primarily with private, state, and federal activities in forest protection in Washington forests during the biennial period ended November 30, 1914.

Annual reports Washington state forester for the years ending November 30, 1915 and November 30, 1916, E. W. FERRIS and F. E. PAPE (*Ann. Rpts. Wash. State Forester, 1915-16, pp. 41, pls. 6*).—These reports deal primarily with fire protection work conducted during 1915 and 1916.

Annual progress report upon state forest administration in South Australia for the year 1915-16, W. GILL (*Ann. Rpt. State Forest Admin. So. Aust., 1915-16, pp. 13, pls. 6*).—A statistical review relative to the administration and management of the state forests of South Australia, including data on alterations in forest areas, planting and other forest operations, revenues, expenditures, etc.

## DISEASES OF PLANTS.

Prophylaxis in vegetable pathology, O. COMES (*La Proflassi nella Patologia Vegetale. Naples: R. Ist. Incoragg. Napoli, 1916, pp. 173*).—This comprises a short introduction, historical in character, and two main sections. The first of these deals with susceptibility as related to climate, soil, cultivation, and nitrogen manuring. The second deals with resistance as related to the various regions of the plant, to the chemistry of the tissues and juices, to oxidases, to selection, and to phosphate fertilizers.

Diseases of cultivated plants. Nonparasitic diseases, G. DELACROIX. Parasitic diseases, G. DELACROIX and A. MABLELANT (*Maladies des Plantes Cultivées. Maladies non Parasitaires. Maladies Parasitaires. Paris: J. B. Ballière*

& Sons, 1916, vol. 1, pp. XII+420, figs. 113; vol. 2, 2. ed., pp. 447, figs. 656).—These volumes form a part of the agricultural series prepared under the direction of G. Wery. The first treats of nonparasitic diseases, or those the causes of which are not definitely known. It also contains chapters on parasitism, symbiosis, immunity, etc.

The second volume describes and discusses bacterial and fungus diseases, as well as the injuries and abnormalities produced by *Cuscuta*, mistletoe, etc. The earlier edition of the second volume has already been noted (E. S. R., 21, p. 146).

Report of the botanist and plant pathologist, H. W. BARRE (*South Carolina Sta. Rpt. 1916*, pp. 16–20).—The lines of investigation reported upon are essentially the same as those previously noted (E. S. R., 34, p. 643).

In the study of cotton anthracnose, methods of securing disease-free seed have been given attention, field selections, hot water treatments, and field tests with old seed having been made. By careful selection, removal of diseased bolls before picking, and the treatment of seed from disease-free stalks with sulphuric acid before planting, it has been found possible to eliminate anthracnose, even from some of the badly diseased varieties. Further tests of old seed kept in the office and laboratories show that three-year-old seed gives disease-free plants. Seed claimed by farmers to have been kept for three years in sheds and barns did not give as satisfactory results as were obtained at the station. Further spraying tests with Bordeaux mixture gave results similar to those reported previously.

The excessive rains during July seriously interfered with the work on the investigation of cotton shedding, but it was found that excessive soil moisture during the blooming season caused as much shedding and as great injury to plants as do long periods of drought. During the past year soil temperatures have been taken, and records of temperatures from different depths are available in connection with other physiological data.

The investigation of the angular leaf spot of cotton has been continued along the same lines as indicated in Bulletin 184 of the station (E. S. R., 35, p. 652), and considerable data secured with reference to the occurrence of the disease, its abundance and spread, methods of dissemination and infection, conditions under which infection takes place, etc.

Brief notes are given of preliminary work on the breeding of cotton, reforestation of the coastal plain, and cooperative experiments with this Department in the production of cotton and cowpeas resistant to wilt and root knot.

Report of the mycological department of the entomological station in Tula for 1913–14, N. P. TRUSOVA (*Abs. in Mat. Mikol. i Fitopatol. Ross.*, 1 (1915), No. 4, pp. 122, 123).—The author gives a list of fungus diseases observed in Province Tula, Russia, in 1913–14, and points out the influence of meteorological conditions on their development. This was especially remarkable in case of the late blight of potatoes, which was very severe in 1913 and practically absent in 1914. Of particular interest is the statement that soda gave satisfactory results in combating the American gooseberry mildew.

Fungus parasites in Province Voronezh collected in the summer of 1912, A. BONDARTSEV (BONDARZEW) and L. DEBEDEVA (*Abs. in Mat. Mikol. i Fitopatol. Ross.*, 1 (1915), No. 4, p. 124).—In connection with descriptions of a number of parasites collected by the authors in the summer of 1912, particular interest is said to attach to the finding of *Peronospora polygoni* on buckwheat, as this may be identical with *Peronospora* sp. found on the same host in France. Many new species are added to the class of imperfect fungi, some of which are illustrated and described.

Some observations on fungus diseases of cultivated plants in Turkestan, N. G. ZAPROMETOV (*Otchet Prakt. Mikol. Turkest. Ent. Sta.*, 1914; *abs. in Mat. Mikol. i Fitopatol. Ross.*, 1 (1915), No. 4, pp. 125, 126).—Special attention was given by the author to diseases which appeared to be very prevalent in orchards and vineyards of Turkestan. Much damage was done to grapevines by the spotted anthracnose, the disease caused by *Cercospora vitiphylla*, and *Oidium*. Among other diseases noted, apple scab and leaf and twig curl of peaches, apricots, and almonds are reported as abundant.

A monograph of the Uredineæ, P. and H. SYDOW (*Monographia Uredinearum seu Specierum Omnium ad Hunc Usque Diem Cognitarum Descriptio et Adumbratio Systematica*. Leipzig: Borntraeger Bros., vol. 3, Nos. 1 (1912), pp. 1-192, figs. 83; 2 (1914), pp. 193-416, figs. 76; 3 (1915), pp. 417-726, figs. 36).—These three numbers deal descriptively and systematically with Pucciniaceæ, Melampsoraceæ, Zaghouniaceæ, and Coleosporiaceæ through the several species.

The wintering of *Coleosporium solidaginis*, E. B. MAINS (*Phytopathology*, 6 (1916), No. 4, pp. 371, 372).—According to the author, *C. solidaginis* has been found wintering over in the rosette leaves of *Solidago* sp., both as mycelium and uredospores.

The mosaic disease of tomatoes and petunias, H. A. ALLARD (*Phytopathology* 6 (1916), No. 4, pp. 328-335, figs. 2).—While engaged in the study of the distribution of the virus causing mosaic disease in tobacco plants, the author also carried on parallel experiments with tomatoes and petunias affected with the same disease.

In comparison with the disease obtained by inoculation with the virus of mosaic-diseased tobacco, tomato or petunia plants inoculated with the virus of other solanaceous plants affected with the mosaic disease show no appreciable difference in the incubation period, symptoms, etc. With the exception of slight variations in the external symptoms produced in these host plants, the author considers that the mosaic disease of tobacco affects the petunia and tomato in quite the same manner as it affects the tobacco plant.

A bacterial disease of western wheat grass (*Agropyron smithii*), P. J. O'GARA (*Phytopathology*, 6 (1916), No. 4, pp. 341-350, pls. 5).—A detailed account is given of an investigation of a bacterial disease of wheat grass due to *Aplanobacter agropyri* n. sp., a preliminary account of which has already been noted (*E. S. R.*, 34, p. 349).

Notes on an artificial culture of *Rhizoctonia crocorum*, W. W. DIEHL (*Phytopathology*, 6 (1916), No. 4, pp. 336-340, fig. 1).—The author reports having grown *R. crocorum* from alfalfa on synthetic media and having found that the fungus made a very slow growth on the media used. The peculiar cultural characteristics of the organism are considered to indicate that its metabolism, in artificial cultures at least, is affected by an accompanying species of *Fusarium*.

Sclerotinia blight, a serious disease of snap beans caused by *S. libertiana*, J. A. McCLINTOCK (*Virginia Truck Sta. Bul.* 20 (1916), pp. 419-428, figs. 4).—A popular account is given of a disease of snap beans caused by *S. libertiana*, which appeared in the vicinity of Norfolk, Va., in 1915. The disease developed after a period of several days of hot, damp weather, and the fungus appeared upon the stems, branches, leaves, and pods, causing considerable loss. In addition to the attack in the field, secondary losses were caused by the fungus on diseased pods spreading to healthy pods in transit to market.

Experiments in the control of the disease showed marked variation in resistance to the blight, some varieties being almost wholly unaffected. For control of the trouble the author recommends the burning over of the fields so as to destroy as much rubbish as possible and the rotation of crops, avoiding

the planting of beans, lettuce, cucumbers, eggplants, etc., which are known to be attacked by this fungus.

**Physiology of *Bacterium malvacearum*, R. C. FAULWETTER** (*South Carolina Sta. Rpt. 1916*, pp. 49-64).—Results of a laboratory study on the physiology of *B. malvacearum*, the cause of the angular leaf spot of cotton, are given, the studies having been conducted in the hope that some insight into the factors as related to parasitism might be secured. In order to obtain data regarding parasitism it is considered important to know the normal physiology of the parasite, its development, dissemination, and control. The author describes the morphology and physiology of the organism when grown in various media, the inhibiting factors of its growth, viability in cultures, etc.

**A rot of endive, J. RITZEMA BOS** (*Tijdschr. Plantenziekten*, 21 (1915), No. 5-6, pp. 169-186).—A rot of endive is described as due to the fungus *Marssonina panattoniana*.

Studies upon the blackleg disease of the potato, with special reference to the relationship of the causal organisms, W. J. MORSE (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 3, pp. 79-126).—After giving a historical review of this potato disease, its character and appearance, geographic distribution, economic aspects, etc., are described. On account of its resemblance to a disease reputed to be due to different species of bacteria, the author has made a study at the Maine Experiment Station of the various organisms that have been isolated and described, in different parts of Europe and Canada, as being the cause of the blackleg of the stem of the potato and the attendant decay of the tubers. For this purpose material for study was obtained of *Bacillus atrosepticus*, *B. phytophthorus*, *B. solanisaprus*, and *B. melanogenes*, comparisons being made with material isolated by the author from diseased potatoes in Maine. The morphology, cultural relations, physical and biochemical characters, and pathogenicity of the different species are described at length.

From the tests made under the same conditions the author concludes that cultures received under the names *B. atrosepticus*, *B. solanisaprus*, and *B. melanogenes*, together with three strains of organisms isolated from potato plants in widely separated parts of Maine are apparently identical and should be classed as one species, or at most, as strains of a single species. The organisms received from two sources, under the name *B. phytophthorus*, proved to be not alike, nor did they agree with that species as originally described.

Concerning the nomenclature of the species the author has adopted the name *B. atrosepticus*, and a revised description of the organism is given.

**Potato wilt and tuber rot caused by *Fusarium eumartii*, R. J. HASKELL** (*Phytopathology*, 6 (1916), No. 4, pp. 321-327, figs. 3).—The author reports on the pathogenicity of a species of *Fusarium* on the vines as well as on the tubers of potato plants.

The disease was first noted on tubers in the winter of 1914, and a fungus isolated which seems to be identical with that described by Carpenter (*E. S. R.*, 34, p. 246). As a result of pure culture inoculations, both in the greenhouse and out-of-doors and on sterilized and unsterilized soil, it is demonstrated that *F. eumartii* may produce both a wilt of the potato vine and a rot of the tuber.

**History and cause of the rind disease of sugar cane, J. R. JOHNSTON** (*Jour. Bd. Comrs. Agr. P. R.*, 1 (1917), No. 1, pp. 17-45, pl. 1).—The symptoms of the rind disease of sugar cane due to *Melanconium sacchari* are described. The author claims that this organism is a wound parasite capable of infecting cane only through wounds or cane that is in an otherwise unhealthy condition. It may, however, become actively parasitic on certain varieties of cane which are characterized by weak, soft growth.

For the prevention of the disease the planting of hardy varieties, the adoption of methods that will reduce the moth borer, and the grinding of cane before it is overripe are recommended. Two related fungi, *M. saccharinum* and *M. iliau*, both of which have been reported as attacking cane, are not considered as causing the rind disease.

A bibliography of the subject is appended.

**Resistance in fruits**, D. РИ́ДВОЙ (*Вѣст. Вред. Сельск. Хоз.* [etc], No. 4, (1915), p. 1; *abs in Mat. Mikol. i Fitopatol Ross.*, 1 (1915), No. 4, pp. 121, 122).—As a result of his studies of the resistance in fruits to apple scab, the author states that smooth and shiny varieties are more susceptible to this disease than those which have dull, rough, or waxy surfaces.

**The root rot disease of the apple in Virginia**, F. D. FROMME and H. E. THOMAS (*Science*, n. ser., 45 (1917), No. 1152, p. 93).—According to the authors, the root rot of apples in Virginia, which is said to be prevalent in the chief orchard districts of the State, is apparently due to a species of *Xylaria*. They report having found perithecial stromata of *X. polymorpha* in various stages of typical root-rot attack, and cultures obtained from this fungus are being used for additional experiments.

**Temperature relations of apple rot fungi**, C. BROOKS and J. S. COOLEY (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 4, pp. 139-164, pls. 3, figs. 25).—A study has been made of a number of species of fungi to determine the temperature relations in connection with the general application of cold storage to fruits. The following species of fungi have been studied at different temperatures and under various conditions: *Alternaria* sp., *Botrytis cinerea*, *Cephalothecium roseum*, *Fusarium radicum*, *Glomerella cingulata*, *Neofabraea malicorticis*, *Penicillium expansum*, *Sclerotinia cinerea*, *Sphaeropsis malorum*, and *Volutella fructi*.

In inoculation experiments with the above species of fungi, all grew at 0° C. except the species of *Fusarium* and *Glomerella*. The former made no growth at 15, and the latter none at 10°. *Sphaeropsis malorum* produced no evident rot in one week's time at 15°, nor *Penicillium* and *Neofabraea* at 10° in two weeks, while *Sclerotinia cinerea* produced measurable rots at 5° in one week, and at 0° in two weeks. The optimum temperature for *N. malicorticis* was 20, for *F. radicum* 30, and for the other fungi 25°. With most of the organisms the growth rate dropped off rapidly above 25, but with the exception of *N. malicorticis* all made some growth at 30°. With most of the fungi the initial incubation stages of growth on the fruit are more inhibited by low temperatures than the later stages, and results obtained show the importance of immediate as compared with delayed cold storage.

**A Phytophthora rot of pear**, T. A. C. SCHOEVEERS (*Tijdschr. Plantenziekten*, 21 (1915), No. 5-6, pp. 153-159).—A rot of pears noted at Bennekom is described, which is thought to be due to *P. omnivora* (*P. cactorum*).

**Peach scab in Netherlands**, T. A. C. SCHOEVEERS (*Tijdschr. Plantenziekten*, 21 (1915), No. 1, pp. 26-29, pl. 1; *abs. in Ztschr. Pflanzenkrankh.*, 25 (1915), No. 6, p. 365).—Black scab spots on peaches in Gendringen contained a fungus said to be *Cladosporium carpophilum*. *Monilia fructigena*, the cause of brown rot, was also present in abundance.

**A root disease of prunes**, MINA A. WILLIS (*Phytopathology*, 6 (1916), No. 4, pp. 368, 369).—The author reports the appearance in the summer of 1915 of a peculiar prune disease in the western part of the Snake River Valley, Idaho. In the early part of the season the trees are said to have been apparently normal, but later they wilted and died. Examination showed the entire root system had been destroyed. The sap from diseased trees had a peculiar odor, from which the local name of sour sap was probably derived.

No organism was found to cause the disease. It is believed that a lack of moisture during the preceding fall and winter had caused the smaller roots to dry and die. After the trees had put out their leaves and formed fruit, the increasing dryness of the air made such demands for water that death of the tree resulted.

[Reports on grape downy mildew] (*Rev. Vit.*, 44 (1916), Nos. 1125, pp. 64-66; 1127, pp. 97, 98; 1128, pp. 114-117; 1129, pp. 121-134; 1130, pp. 137-156).—This continues an account of reports from various sections on downy mildew, as made in 1915 and noted previously (*E. S. R.*, 35, p. 352). This is considered the most important body of information yet collected on this subject, on account of the extent of territory involved and the number, scope, and character of the responses made to requests for information, as noted below.

The development and the treatment of downy mildew in 1915, J. CAPUS (*Rev. Vit.*, 44 (1916), Nos. 1131, pp. 157-162; 1132, pp. 181-190, figs. 2; 1133, pp. 201-206, fig. 1; 1134, pp. 217-224; 1135, pp. 237-247, figs. 2; 1136, pp. 253-255; 1138, pp. 289-303; 1140, pp. 325-334, figs. 2; 1141, pp. 341-350; 1142, pp. 357-363; *abs. in Compt. Rend. Acad. Agr. France*, 2 (1916), No. 22, pp. 619-621).—Analyzing the large body of information which is noted above, the author gives a compact summary of certain portions with some practical conclusions as deduced therefrom.

It is stated that in spite of the exceptional severity of attacks and of the economic situation in 1915, a number of vine growers were able to save their crops largely or entirely. As in previous years, the preservation of the vines as against mildew was found to depend upon such circumstances as the time of treatment, the proportion of copper employed, and the care used in spreading the fungicides, among which first rank was held by Bordeaux and Burgundy mixture and copper acetate solution.

As usual, there was a period of a few days just previous to the outbreak during which the treatment could be applied with assurance of its absolute efficacy. This favorable period is related, in case of a primary outbreak, to a period of precipitation. Secondary invasions are related to a rain or period of precipitation following a primary invasion. The determination and utilization of a period favorable for treatment requires the services of a specialist for each region, and its efficacy also depends upon the carefulness and thoroughness of its employment.

In the absence of such special information, a fair degree of success has been attained by thorough and careful spraying each time that the conditions led to new growth of the vines. Protection of the grapes requires very careful spraying during the period of inflorescence. The duration of effectiveness of the spray is dependent largely upon the abundance of the spray and upon its copper content. With the exception of certain cases, in which a 1 per cent solution appears to be effective, a strength of 2 per cent is considered to be the lowest that is safe, at least for general practice, especially in years when conditions are such as to favor serious outbreaks, as in 1910 and 1915. For infrequent treatment or late final treatment, a strength of 3 per cent is considered preferable.

Casein is the only material that has up to this time been extensively used in ordinary practice to increase the adherence of the fungicides, but the results from this are said to be satisfactory. Copper fungicides in the form of powders are reliable as regards fungicidal results, when employed at a favorable time. They are not so lasting as are the sprays, but they cause less injury to the fruits. A number of viticulturists employ powdered preparations immediately following the spray. No general superiority of acid

sprays, as such, has been demonstrated by these reports, as practically the same results were obtained by the use of neutral or basic preparations.

**Diseases of grapevines in Vardar, P. VIALA** (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 20, pp. 561-564; *Rev. Vit.*, 44 (1916), No. 1146, pp. 425-427).—Giving an account of some parasites injurious to grape stocks in parts of southern Europe and northern Africa, the author describes an attack by a termite (*Calotermes lucifugus*), which, particularly in the hill region of Vardar, enters (by way of the quickly dried and hence poorly cicatrized wounds left by pruning) into the pith and adjacent tissue of grape stock, and is often accompanied by a polyporous fungus (noted also in France), which, if unchecked, destroys the vine in five or six years. An arsenical treatment has been successfully used for both the animal and the fungus parasite. The fungus is said to be very sensitive to the action of oxygen, and is also said to have been controlled for years in some regions by splitting the stock and inserting a stone to keep the wound open to the air, this treatment causing the death of the parasitic fungus.

**Grape diseases in Greece, P. VIALA** (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 26, pp. 723-725).—The author quotes a communication from Genadius addressed to the Academy of Agriculture, in which it is claimed that the procedure above described, though indeed very old, as are others described, is designed only to check too luxuriant vegetation and restore the full fruiting capacity of the vines, various selections from earlier writings being quoted in this connection.

**Observations on the distribution of citrus canker, D. B. MACKIE** (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 4, pp. 278-281, pl. 1).—The author and some of his associates have made a survey of the Philippines to determine the distribution of the citrus canker, and have found the disease present in a number of localities, occurring on different species of Citrus. The presence of the disease in these localities can in many instances be traced to shipments of plants from Manila. The conclusion is reached that, as the disease has not been found in the more remote districts, its introduction into the islands is comparatively recent.

**Spore variation in Neopeckia coulteri, J. S. BOYCE** (*Phytopathology*, 6 (1916), No. 4, pp. 357-359).—While examining collections of *N. coulteri*, the author reports having observed several of the spores to have become two-septate and sometimes three-septate by the formation of secondary septa. This led to a study of other collections, from which it appears that such behavior of the spores is not uncommon. The triseptate spores of *Neopeckia* and spores from a species of *Herpotrichia* on *Primula* suggest a very close relationship of the two fungi.

**Preliminary note on the occurrence of Peridermium balsameum in Washington, H. SCHMITZ** (*Phytopathology*, 6 (1916), No. 4, pp. 369-371, figs. 2).—The author reports the occurrence of this rust on the seedlings of *Abies amabilis*. It is said that this is the first record of the species west of the Mississippi Valley.

**A successful inoculation of Abies lasiocarpa with Pucciniastrum pustulatum, J. R. WEIR and E. E. HUBERT** (*Phytopathology*, 6 (1916), No. 4, p. 373).—The authors have successfully inoculated young needles of *A. lasiocarpa* with *P. pustulatum*, collected on overwintered leaves of *Epilobium angustifolium*.

**Successful inoculations of Larix occidentalis and L. europea with Melampyris bigelowii, J. R. WEIR and E. E. HUBERT** (*Phytopathology*, 6 (1916), No. 4, pp. 372, 373).—Successful inoculations of the above species of *Larix* with teliospores of *M. bigelowii* from a willow are reported.

Work on the white pine blister rust in Minnesota, 1916, F. L. WASHBURN ([*Minn. State Ent. Dept.*] *Circ. 40 (1916)*, pp. 19, pl. 1, figs. 6).—An account is given of work carried on in the summer of 1916 for the eradication of the white pine blister rust, the presence of which was definitely established in a few counties in Minnesota adjacent to the Mississippi River.

The white pine blister rust. Does the fungus winter on the currant? W. A. McCUBBIN (*Science, n. ser.*, 45 (1917), No. 1152, p. 87).—Data are presented that are considered to indicate that the white pine blister rust may winter over on the currant under certain conditions.

*Keithia thujina*, the cause of a serious leaf disease of the western red cedar, J. R. WEIR (*Phytopathology*, 6 (1916), No. 4, pp. 360–363, figs. 2).—The author reports observing a serious leaf disease on the western red cedar (*Thuja plicata*), in the lake region of northern Idaho.

An examination of the material showed that the disease was due to *K. thujina*. This fungus is considered primarily one which attacks seedlings and young trees, but the foliage of the upper crown of forest trees may also be infected, although not to the same extent as the leaves on branches nearer the ground. Evidence is presented which indicates that snow may be a factor in promoting the growth of the organism, as it is particularly noticeable where seedlings remain covered with snow until late spring. A preliminary experiment indicates that the disease may be held in check by spraying seedlings in nurseries with a rather strong soap-Bordeaux mixture.

Note on "spike" disease in sandal, P. M. LUSHINGTON (*Indian Forester*, 42 (1916), No. 2, pp. 61–65).—Summarizing what is known of spike in sandal, the author states that it was described, investigated, and reported on in 1902, having at that time been prevalent in Coorg for four or five years.

The disease appears to be very infectious and to spread rapidly. It is thought that birds or insects may possibly be instrumental in spreading it, and no tree once diseased in this way has been known to recover. Observations by a number of persons are given on the various phases of the disease and on different plants showing a similar abnormality. It is stated that in the Kollimalais sandal has been found to be considerably attacked by *Viscum verruculosum*.

A possible cause of "spike" in sandal, T. A. WHITEHEAD (*Indian Forester*, 42 (1916), No. 5, pp. 243–247).—The view is advanced, with supporting observations, that the cause of spike in sandal is undue reduction in the supply of water to the plant in proportion to its growing needs. The suckers produced from the injured roots of an affected tree show the same trouble as do also root suckers which spring up where a spiked tree has been dug up. The degree of the trouble is the same throughout the tree at a given time. When death sets in the ends of the shoots die before the branches. The so-called phyllode in spiked trees is associated with excess starch in stems, twigs, and leaves. It is stated that no spiked tree has been known to recover.

No fungus has been found in connection with the spike disease and no transmission of the disease has been accomplished experimentally. In spiked trees the root ends die and the haustoria are found to be either absent or dead. Both diseased and healthy trees may bear scars, evidencing parasitism. In one case a living haustorium was found on a diseased tree.

Spike has been observed in other trees noted. The rapid spread of the disease, observed by Lushington as noted above, is thought to be due to the overtaxing of a given area by sandal and the consequent relative exhaustion of its means of obtaining water. Spike is thought to be not a disease, but a symptom of increasing inadequacy in the means of securing water. The remedy

suggested is to plant more trees that may serve as hosts or to thin out the sandal.

The occurrence of bamboo smut in America, FLORA W. PATERSON and VERA K. CHARLES (*Phytopathology*, 6 (1916), No. 4, pp. 351-356, fig. 1).—The authors report the occurrence of *Ustilago shiraiana* on *Phyllostachys henonis* grown at Chico, Cal., from importations made from Japan.

### ECONOMIC ZOOLOGY—ENTOMOLOGY.

Annual report of the governor of Alaska on the Alaska game law, 1916, J. F. A. STRONG (*U. S. Dept. Agr., Bur. Biol. Survey Doc. 105 (1917), pp. 16*).—This, the fourth annual report on the administration of the Alaska game law, covers the fiscal year ended June 30, 1916. Information for the public in regard to the Alaska game law and regulations of the Department of Agriculture, regulations relative to licensed guides and packers in the Kenai Peninsula, and laws passed by the 1915 session of the Alaska territorial legislature for the protection of game animals are contained in appendixes.

The domestic cat, E. H. FORBUSH (*Mass. Bd. Agr., Econ. Biol. Bul. 2 (1916), pp. 112, pls. 21, figs. 21*).—This article deals with the cat as a bird killer, mouser, and destroyer of wild life and discusses means of utilizing and controlling it.

Rats and rat riddance, E. H. FORBUSH (*Mass. Bd. Agr., Econ. Biol. Bul. 1 (1915), pp. 87, pls. 12, figs. 19*).—Previously noted from another source (*E. S. R.*, 35, p. 656).

Bacterium tularense (*Pub. Health Rpts. [U. S.], 31 (1916), No. 17, pp. 1045, 1046*).—This plague-like disease, not uncommon among ground squirrels in California, was observed in a rabbit in March by M. T. Clegg, this being the first record for California. An outbreak of the disease in rabbits in Indiana has been previously reported by Wherry (*E. S. R.*, 33, p. 450).

Land birds of northern New York, E. J. SAWYER (*Watertown, N. Y.: Watertown Bird Club, 1916, pp. 90, pl. 1, figs. 32; rev. in Auk, 33 (1916), No. 4, p. 442*).—A pocket guide to common land birds of the St. Lawrence Valley and the lowlands in general of northern New York.

The food of West Virginia birds, E. A. BROOKS (*W. Va. Dept. Agr. Bul. 15 (1916), pp. 74, pls. 3, figs. 17*).—A study of the economic value of birds of West Virginia, with suggestions for the protection of the most useful species.

The birds of the Isle of Pines, W. E. C. TODD (*Ann. Carnegie Mus., 10 (1916), No. 1-2, pp. 146-296, pls. 6; abs. in Auk, 33 (1916), No. 3, pp. 332, 333*).—This work, incorporating the substance of field notes by G. A. Link and consisting largely of an annotated list of 142 species, includes an outline of the geography and physiography of the Isle of Pines; notes on the climate, previous work, seasonal occurrence, and faunal affinities; a bibliography of 64 titles; etc.

Some common insects and plant diseases of the farm, garden, and orchard, W. E. RUMSEY (*W. Va. Dept. Agr. Bul. 17 (1916), pp. 38, figs. 69*).—A popular illustrated account of the more important insects and plant diseases in West Virginia.

One hundred notes on Indian insects, T. B. FLETCHER (*Agr. Research Inst. Pusa Bul. 59 (1916), pp. V+39, figs. 20*).—These notes relate to insects of economic importance.

[Insects and control measures in South Africa] (*Union So. Africa Dept. Agr. [Pub.], 1915, Nos. 75, pp. 8; 83, pp. 8, figs. 8; 1916, Nos. 5, pp. 10, figs. 4; 6, pp. 7, figs. 6; 7, pp. 7, figs. 4; 8, pp. 8, figs. 8; 9, pp. 6*).—These papers on insect pests and their control in South Africa relate, respectively, to Locust Destruction; The Mally Fruit Fly Remedy for the Prevention of Maggots in Fruit by the

Destruction of the Parent Flies Before Eggs Are Laid; and The Pepper Tree Caterpillar (*Bombycomorpha pallida*), The Potato Ladybird Beetle (*Epilachna dregei*), The Plum Slug Caterpillar (*Parasa latistriga*), (I) Some Destructive Fruit and Flower Beetles, (II) A New Insect Pest of the Peach (*Philagathes latus*), and The Cucumber and Vegetable Marrow Fly (*Dacus vertebratus*), by D. Gunn.

Notes on insects damaging sugar cane in Queensland, E. JARVIS (*Bur. Sugar Expt. Stas. Queensland, Div. Ent. Bul. 3* (1916), pp. 48, figs. 57).—This is a brief record of field and other observations made of the insect enemies of sugar cane, largely in the vicinity of Gordonvale.

Revision of the Japanese termites, S. HOZAWA (*Jour. Col. Sci. Imp. Univ. Tokyo, 35* (1915), Art. 7, pp. 161, pls. 4, figs. 39).—This revision, in which 13 species are recognized, includes a table showing their distribution in Japan and a list of the literature on the Japanese species, together with colored figures of most of the species.

Experiments on the transmission of infantile leishmaniasis by fleas (*Pulex irritans*), PEREIRA DA SILVA (*Arg. Inst. Bact. Camara Pestana, 4* (1916), No. 3, pp. 261-267).—The author's investigations have led to the conclusion that thus far it has not been demonstrated that fleas (*Ctenocephalus canis* and *P. irritans*) act as agents in the transmission of human and canine leishmaniasis.

Native food plants and feeding habits of the cotton stainer in St. Vincent (*Agr. News [Barbados], 15* (1916), Nos. 369, pp. 202, 203; 370, p. 218).—Investigations made of *Dysdercus delauneyi* in districts where Sea Island cotton is grown on an extensive scale show that at the end of February, when the fields are being cleaned of the old cotton plants, it migrates to trees, bushes, and herbaceous plants nearby. It feeds on flowers of the mango (*Mangifera indica*), *Eupatorium odoratum*, black sage (*Cordia cylindristachya*), and horse-radish tree (*Moringa pterygosperma*), the fruit of okra (*Hibiscus esculentus*) and maiden's blush (*Mormordica charantia*), and secretions of scale insects, but does not appear to be able to breed thereon. Its occurrence on two malvaceous food plants other than cotton, namely, the silk cotton tree (*Eriodendron anfractuosum*) and the John Bull tree (*Thespesia populnea*) which are its chief food plants in the close season for cultivated cotton, is considered at some length.

Additional notes on the native food plants and feeding habits of the cotton stainer in St. Vincent (*Agr. News [Barbados], 15* (1916), No. 373, p. 267).—With further observations of *Dysdercus delauneyi*, an account of the food plants and feeding habits of which is above noted, the infestation of young cotton fields has been definitely traced to the silk cotton tree (*Eriodendron anfractuosum*) and the John Bull tree (*Thespesia populnea*). A campaign of control will consist at first in the destruction of the John Bull trees.

Key to the nearctic species of *Paracalocoris* (Heteroptera; Miridæ), W. L. McATEE (*Ann. Ent. Soc. Amer., 9* (1916), No. 4, pp. 366-390).—The key given to this genus of the subfamily Mirinæ includes 10 species of which 4 are new and 26 varieties of which 23 are new. Among the more important are *Paracalocoris scrupeus cunealis* n. var., occurring on wild apple, Cratægus, and quince at Batavia, N. Y., and *P. hawleyi ancora* n. sp. and n. var., reported by I. M. Hawley as becoming a pest of economic importance on the cultivated hop near Waterville, N. Y., where he has worked out its life history.

The leafhoppers or Jassoidea of Tennessee, D. M. DeLONG (*Tenn. Bd. Ent. Bul. 17* (1916), pp. 113, figs. 24).—This work, which includes keys to the families, genera, and species of leafhoppers occurring in Tennessee, lists and describes 212 species and varieties.

Observations on the ecology of Coccidæ, with special reference to their morphology and physiology, G. TEODORO (*Redia*, 11 (1916), No. 1-2, pp. 129-209, pls. 3, figs. 3).—This discussion includes a bibliography of 100 titles.

Researches and experiments in the control of *Chrysomphalus dictyospermi* of citrus in Sicily in 1914, G. DEL GUERCIO and E. MALENOTTI (*Redia*, 11 (1916), No. 1-2, pp. 1-127, pl. 1, figs. 25).—Though reporting largely upon control work with insecticides, the biology of the "bianca-rossa" is briefly considered.

Statistics on the production of silk in France and elsewhere (*Statistique de la Production de la Soie en France et a l'Étranger*. Lyon: Syndicat de l'Union des Marchands de Soie de Lyon, 1916, pp. 78).—Statistical data on silk production during 1914 in occidental Europe, the Levant and central Asia, and the extreme Orient are here presented. See also a previous note (E. S. R., 35, p. 56).

The white-marked tussock moth, R. L. WEBSTER (*Iowa Sta. Circ.* 33 (1916), pp. 4, figs. 3).—Numerous reports of the abundance of this pest in Iowa received during the fall of 1916 led to the preparation of this brief account.

The potato tuber moth, J. E. GRAF (*U. S. Dept. Agr. Bul.* 427 (1917), pp. 56, pl. 1, figs. 45).—This is a report of investigations of the potato tuber worm conducted in southern California from 1912 to 1916, a general account of which pest by Chittenden has been noted (E. S. R., 29, p. 855.)

This moth injures the potato by destroying the leaf surface and tunneling in the substance of the tuber. The tuber-feeding larva injures the potatoes themselves by tunneling through them, so filling these tunnels with excrement and fungus that the potatoes, even if not severely injured, are very unsightly and of small market value. It is a source of serious injury to other plants as well, including eggplant, tomato, red pepper, tobacco, etc.

The life history studies here reported upon at length show that in southern California there are five or six generations, all stages occurring at all times of the year. Parasites, while varying in effectiveness, play an important part in checking the pest, the egg and pupa each having its parasite, while several attack the partially grown larvæ and at least two the mature larvæ. Since the burrowing habit of the larva protects it from parasites, except while spinning its cocoon and pupating, it is doubtful if parasites can be of practical importance when the insect infests stored tubers. During 1914 *Habrobracon johannseni* was the most effective parasite, their order of importance in that year being as follows: *H. johannseni*, *Chelonus shoshoneanorum*, *Sympiesis stigmatipennis*, *Campoplex phthorimæ*, *Bassus gibbosus*, *Apanteles* sp., *Microgaster* sp., *Nepeira benevola fuscifemora*, and *Zagrammosoma flavolineatum*. During 1915 *Dibrachys clisiocampæ*, *S. stigmatipennis*, and *C. phthorimæ* were of first and about equal importance. Observations of a secondary parasite, *D. boucheanus*, and the parasites above mentioned are recorded in connection with illustrations of each.

Data relating to control measures have been summarized as follows:

"The numbers of the insect should be reduced by practicing good farming and leaving no tubers exposed for the insect to work on. Potatoes should be harvested and marketed as rapidly as possible, unless the grower has facilities for storage and is prepared to treat the potatoes if necessary. Once the tubers become infested, the best way of ending the damage is to fumigate with carbon bisulphid, using 2 lbs. to 1,000 cu. ft. of air space (measured before storing the tubers) and allowing 48 hours for fumigation. Clean or uninfested potatoes should be kept away from the moth.

"Potatoes should never be left in the ground after they are ripe and where the soil is dry. When tubers are infested and facilities are lacking for storing

in bins, the progress of infestation can be checked by holding the potatoes in cold storage. The temperature should be about 37 to 40° F. This should be adopted only as a temporary method in keeping potatoes from deteriorating in value while they are being held for a rise in price."

A map showing the localities in which the potato moth is established on potato, localities in which it is established on other plants, and localities where it has been introduced but is not established is attached. A bibliography of 96 titles is included.

The rhododendron tingid (*Stephanitis rhododendri*) in Surrey, E. E. GREEN (*Ent. Mo. Mag.*, 3. ser., 2 (1916), No. 21, pp. 207, 208).—The author records the occurrence of this pest at Camberley.

A note by G. C. Champion appended calls attention to the fact that *Leptobyrssa explanata*, described by Heidemann in 1908 as occurring abundantly on mountain laurel (*Kalmia latifolia*) and injuring the foliage of *Rhododendron maximum* along the Atlantic coast of the United States (E. S. R., 21, p. 451), is certainly the same species. An account of the life history of *L. explanata* by Crosby and Hadley has been previously noted (E. S. R., 34, p. 451).

Observations of the biology of *Recurvaria nanella*, A. MIGNONE (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 3, pp. 188-195).—This is a preliminary report of studies of the lesser bud moth in Italy. Studies of this pest by Houghton in England (E. S. R., 15, p. 787) and by Scott and Paine in the United States (E. S. R., 31, pp. 252, 755) have been previously noted.

Evolution of the color pattern in the microlepidopterous genus *Lithocolletis*, ANNETTE F. BRAUN (*Jour. Acad. Nat. Sci. Phila.*, 2. ser., 16 (1915), pp. 105-166, pls. 2, figs. 26).—Among the species listed, in which the development of the pattern has been traced from the first appearance of color to the adult markings, *Lithocolletis cratagella* is of economic importance.

Neuropteroid insects of the Philippine Islands, N. BANKS (*Philippine Jour. Sci., Sect. D*, 11 (1916), No. 3, pp. 195-217, pls. 2).

The control of the house fly, R. BLANCHARD (*Ligue Sanit. Franç. Bul.* 5 (1915), pp. 63, figs. 27; abs. in *Jour. Roy. Army Med. Corps*, 26 (1916), No. 2, pp. 248-254, figs. 3).—A general discussion of the subject, of the more important species occurring in the house, their manner of reproduction, diseases transmitted, and control measures. A discussion by H. G. Richter of the manner of arranging manure heaps in order to destroy the fly larvæ contained therein is appended (pp. 59-62).

Prevention of fly breeding in horse manure, S. M. COPEMAN (*Lancet [London]*, 1916, I, No. 24, pp. 1182-1184, figs. 2).—The author reports experiments with the "close-packing" method of controlling the house fly in horse manure about military camps.

It was found that the temperature developed during fermentation largely depended on the manner in which the manure was stacked during the building of the heap. In temperature experiments by F. M. Howlett maggots were found to be killed quickly by either dry or wet heat at any temperature above 114.8° F., and he considers it improbable that they could live long at any temperature above 106°. Records kept of temperatures in piles of manure showed that at no great depth from the surface the heat was too great to permit the existence of larvæ. On the top of the piles the larvæ were living only in the surface layers, and the excessive heat due to fermentation becomes practically a larvicide.

Some experiments on the house fly in relation to the farm manure heap, H. ELTRINGHAM (*Jour. Agr. Sci. [England]*, 7 (1916), No. 4, pp. 448-457, figs. 3).—This is a report of a series of experiments conducted with a view to test-

ing the fly-breeding capacity of the open farm manure heap as distinguished from heaps in close proximity to dwellings. The conclusions drawn which apply to manure heaps far distant from houses are as follows:

While the house fly is liable to breed in large numbers in stable refuse which is stored in close proximity to dwellings, the governing factor is found in the dwellings rather than in the manure heap, the latter merely serving as a secondary convenience, providing a breeding place for the flies which have been attracted to the houses in search of food. The open farm manure heap far away from houses is but little frequented by house flies, and then only later in the season when the insect has become numerous and widely dispersed. The spent manure heap, in which fermentation has practically ceased, produces under rural conditions at least practically no flies at all. Although the farm heap may produce but few house flies, it is a prolific source of *Stomoxys calcitrans*, and those agriculturists who value the comfort and health of their animals should treat all manure with a view to the destruction of the larvæ of this pest.

A note on some helminthic diseases with special reference to the house fly as a natural carrier of the ova, T. O. SHIRCORE (*Parasitology*, 8 (1916), No. 3, pp. 239-243).—The data presented show the house fly to be an important factor in the conveyance of the ova of helminths.

Filariasis.—Report of two cases in the District of Columbia and analysis of the cases reported for eastern North America, M. W. LYON, JR. (*Jour. Amer. Med. Assoc.*, 68 (1917), No. 2, pp. 118, 119).—In reporting upon two cases of infection with *Filaria bancrofti* in the District of Columbia it is pointed out that *Culex quinquefasciatus*, the mosquito which serves as the intermediate host of *F. bancrofti*, ranges as far north as Washington and St. Louis, and perhaps farther.

A new enemy of maguey, G. GANDARA (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 32 (1915), No. 11-12, pp. 483-489, figs. 5).—An account of (*Trypeta*) *Myennis scutellaris*, which is a source of injury to the agave in Mexico.

The cabbage root maggot and its control in Canada, with notes on the imported onion maggot and the seed-corn maggot, A. GIBSON and R. C. TREHERNE (*Canada Dept. Agr., Ent. Branch Bul.* 12 (1916), pp. 58, pl. 1, figs. 29).—This bulletin reports studies of the biology of the cabbage maggot and of control measures made at Agassiz, British Columbia, and at Ottawa, Ontario. It records observations made of the depth of puparia in the soil, emergence of flies from puparia buried at different depths, the length of the puparium stage during summer and autumn, length of the life of individual flies, development, habits, and reproduction, and gives a chart which shows the egg deposition of the cabbage maggot at Agassiz in 1915, with records of prevailing temperature, rain, etc.

Short accounts of the life history, habits, and reproduction of the imported onion maggot or *Hylemyia antiqua* (*Phorbia cepetorum*) and of the seed-corn maggot (*P. fusciceps*) follow.

The means of controlling root maggots considered include the use of tar paper disks (E. S. R., 31, p. 352; 35, pp. 53, 55), cheesecloth frames (E. S. R., 25, p. 38), trap crops, etc. The bulletin concludes with a discussion of the control of root maggots under field conditions.

The parasites of maggots reared in Canada are a staphylinid (*Baryodma ontarionis*), long known in eastern Canada as an enemy of the cabbage root maggot; a cynipid (*Cothonaspis gillettei*), which has a wide distribution in the Dominion; a chalcidid (*Pachycrepoides dubius*); and what is thought to be *Hemiteles ruficornis*. The predators, which were found under laboratory conditions to readily devour the eggs, larvæ, and often the hard-shelled puparia,

are *Bembidium mutatum*, *B. trechiforme*, *Platynus cupreus*, *Pterostichus lucublandus*, and *Amara (Celia) farcta*. Other species recorded as probably predacious at Agassiz are *Orus punctatus*, *Xantholinus hamatus*, *Hesperobium californicum*, *Dinaraea angustula*, and a red mite.

Some experiments on the breeding of the mangold fly (*Pegomya hyoscyami*) and the dock fly (*P. bicolor*), A. E. CAMERON (*Bul. Ent. Research*, 7 (1916), No. 1, pp. 87-92, figs. 2).—The experiments here reported have led the author to the conclusion that "*P. hyoscyami* reared on belladonna will oviposit and complete its life history on mangolds if belladonna be absent. Why this same species did not oviposit on the leaves of sugar beet was not discovered. *P. hyoscyami* reared on mangold leaves did not oviposit on those of the very closely allied sugar beet. All that can be inferred from the experiment is that the species when reared on the leaves of the mangold will more readily oviposit on those of the same plant than on sugar beet.

"*P. bicolor* reared on dock does not oviposit and complete its life history on the leaves of the mangold or sugar beet. It may also be safely asserted that neither does *P. hyoscyami* reared on mangold or sugar-beet leaves oviposit on those of the dock.

"Where weeds and cultivated plants have their leaves similarly blotched and blistered by leaf-mining maggots, one must make a careful examination of the insects before stating that the damage is due to one and the same agent. The author believes that hasty and immature judgment has led to the commonly accepted error that the maggot (*P. bicolor*) which mines in the leaves of the dock also attacks those of mangolds. That the insect which blisters the leaves of the common weed, goosefoot (*Chenopodium album*), is identical with the *P. hyoscyami* which causes similar injury to mangold leaves, there is no doubt. In how far there may be a migration, if any, of the insects between the two plants has not been experimentally established."

An account of the life history of *P. hyoscyami* by the author has been previously noted (E. S. R., 32, p. 351).

A new species of *Agromyza* destructive to beans in the Philippines, J. R. MALLOCH (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 2, p. 93).—*Agromyza destructor*, which is very destructive to beans in the Philippine Islands through working in the stems of young plants, is described as new.

The scarabeid enemies of sugar cane, C. MOREIRA (*Os Besouros da Cana de Assucar. Rio de Janeiro: Min. Agr., Indus., e Com.*, 1916, pp. 25, figs. 22).—A brief account of the more important white grubs injuring sugar cane in Brazil and means for their control, with a note on other sugar cane pests.

On the value of poison bait for controlling cane grubs, E. JARVIS (*Bur. Sugar Expt. Stas. Queensland, Div. Ent. Bul.* 4 (1916), pp. 14, figs. 9).—A report of laboratory tests of poison bait for the control of the grey-back cane beetle (*Lepidiota albohirta*), a serious pest of sugar cane.

A generic synopsis of the coccinellid larvæ in the United States National Museum, with a description of the larva of *Hyperaspis binotata*, A. BÖVING (*Proc. U. S. Nat. Mus.*, 51 (1917), pp. 621-650, pls. 4).—This paper includes a bibliography of ten pages.

A bad attack by the mustard beetle on water cress, A. ROEBUCK (*Jour. Bd. Agr. [London]*, 23 (1916), No. 3, pp. 238-241, pl. 1).—*Phædon cochlearia* has been the source of severe injury to water cress on a Shropshire farm.

The desert corn flea-beetle, V. L. WILDERMUTH (*U. S. Dept. Agr. Bul.* 436 (1917), pp. 21, pl. 1, figs. 7).—This is a report of studies of the biology and methods of control of *Chætocnema ectypa* commenced in the Imperial Valley of California in 1910 and carried on during 1913, 1914, and 1915 at Tempe, Ariz.

This flea-beetle occurs in injurious numbers in the cultivated areas of the

Southwestern States on corn, milo maize, sugar cane, Sudan grass, wheat, barley, and alfalfa. The adult is a source of injury through feeding upon the top of the plant and the larvæ upon the roots.

"The eggs are deposited at or near the surface of the ground and hatch in about six days. The young larvæ are found within the tender roots of the food plants, while the older larvæ are found in the soil near these roots. The average length of the larval stage is found to be 32 days. The prepupal and pupal stages are both passed within a cell in the soil near to the roots on which the larvæ fed. The flea-beetles hibernate in the adult stage under rubbish or at the base of various grasses growing in the regions of infestation. The total length of the life cycle of this flea-beetle is about seven weeks, there being from three to four generations each year.

"The numbers of adult flea-beetles can be reduced greatly by cleaning up hibernation quarters and eradicating some of their weed food plants, such as Johnson grass, salt grass, and Bermuda grass. They can be further reduced by carefully cultivating such crops as can be cultivated just as soon as the soil becomes dry, following each irrigation. This method destroys a great many pupæ. Small pieces of corn can be sprayed successfully with arsenate of lead, using 2 lbs. to 50 gal. of water, the water being made into a strong soap solution. This acts both as a repellent and as a poison to the beetles. Injury to corn and other crops can be overcome partially if the soil is placed in the best possible cultural condition by the addition of barnyard manure or other fertilizer. The nymphs and adults of a predacious hemipteran (*Reduvius fesus*) were observed to feed upon these beetles, and a small parasitic wasp, *Neurepyris* sp., was found to prey upon the larvæ and prepupæ."

Borers infesting the ash, F. J. SEAVER (*Jour. N. Y. Bot. Gard.*, 17 (1916), No. 199, pp. 95-97, pls. 2).—A brief account of the life history of and injury caused by the ash borer (*Podosesia syringæ*), which is a close rival of the leopard moth in its destruction of the ash.

A new species of *Pityogenes*, J. M. SWAINE (*Syracuse Univ. [Pubs.]*, 16 (1915), No. 1, pp. 8-10).—The species here described as new, *Pityogenes hopkinsi*, is the most abundant bark beetle in the limbs of pine throughout the eastern part of Canada and the United States. A second species is described as *P. lecontei* n. sp.

Observations on the life history and habits of *Pityogenes hopkinsi*, M. W. BLACKMAN (*Syracuse Univ. [Pubs.]*, 16 (1915), No. 1, pp. 11-66, pls. 6).—The author here reports studies of the life history and bionomics of the species above described as new to science.

Thirty-sixth annual report of the Beekeepers' Association of the Province of Ontario, 1915 (*Ann. Rpt. Beekeepers' Assoc. Ontario, 1915*, pp. 92, figs. 8).—This report of the proceedings of the association includes papers on Temperature and Humidity in the Hive in Winter, by E. F. Phillips (pp. 10-27); Honey Production from the Golden-rods and Asters, by F. W. L. Sladen (pp. 27-30); Outdoor Wintering, by H. G. Sibbald (pp. 30-38); Notes from the Year's Work, 1915, by M. Pettit (pp. 38-46); etc.

Sacbrood, G. F. WHITE (*U. S. Dept. Agr. Bul.* 431 (1917), pp. 54, pls. 4, figs. 33).—This is a detailed report of investigations of an infectious disease of the brood of bees which is caused by a filterable virus, as described in the preliminary report previously noted (*E. S. R.*, 29, p. 57).

The author has found that a colony can be inoculated by feeding it sirup or honey containing the virus, that the quantity of virus contained in a single larva recently dead of the disease is sufficient to produce quite a large amount of sacbrood in a colony, and that the incubation period is approximately six days, though frequently slightly less. While the disease is more often en-

countered during the first half of the brood-rearing season than during the second half, it may be produced by inoculation at any season of the year that brood is being reared. "It occurs among bees in localities having as wide a range of climatic conditions, at least, as are found in the United States. The course of the disease is not greatly affected by the character or quantity of the food obtained and used by the bees. Larval remains recently dead of the disease prove to be very infectious when fed to bees. Dead larvæ which have been in the brood comb more than one month are apparently noninfectious. Colonies possess a strong tendency to recover from the disease without treatment.

"The virus of sacbrood suspended in water and heated to 138° F. (59° C.) was destroyed in 10 minutes. Considering the varying factors which enter into the problem, the minimum temperature necessary to destroy this virus when applied for 10 minutes should be found at all times to lie somewhere between the limits of 131 and 149° F. When the virus of sacbrood is suspended in honey it may be destroyed by heating the suspension for 10 minutes at approximately 158°."

The virus resisted drying at room temperature for approximately three weeks. It was destroyed by the direct rays of the sun in from four to seven hours when dry, when suspended in water in from four to six hours, and when suspended in honey in from five to six hours. When suspended in honey and shielded from direct sunlight it remained virulent for slightly less than one month at room temperature during the summer. The virus was destroyed in approximately five days in the presence of fermentative processes taking place in 10 per cent sugar solution at room temperature.

"In the presence of fermentative processes going on in 20 per cent honey solution at outdoor temperature the virus of sacbrood was destroyed in approximately five days. In the presence of putrefactive processes the virus remained virulent for approximately 10 days. The virus will resist 0.5 per cent, 1 per cent, and 2 per cent aqueous solutions of carbolic acid, respectively, for more than three weeks, 4 per cent being more effective. Neither carbolic acid nor quinin as drugs should at present be relied upon in the treatment of sacbrood.

"Varying factors entering into many of the problems discussed in this paper tend to vary the results obtained. In such problems the results here given must be considered from a technical point of view as being approximate only. They are sufficiently exact for application by the beekeeper, but to insure the destruction of the virus in practical apiculture the time element indicated from these experiments as sufficient should be increased somewhat."

Descriptions of seven new species of red spiders, E. A. MCGREGOR (*Proc. U. S. Nat. Mus.*, 51 (1917), pp. 581-590, pls. 7).—Six species of *Tetranychus* and one of *Tetranychina* are here described as new to science. Of the former, two are from South America and four from North America. *Tetranychus ilicus* discolors the leaves of American holly, *T. willamettei* injures at times the appearance of the western white oak, and *T. monticolus* saps the vitality of the large huckleberry of the Cascade region.

A case of infestation with *Dipylidium caninum*, MARIA P. MENDOZA-GUAZON (*Philippine Jour. Sci.*, Sect. B, 11 (1916), No. 1, pp. 19-31, figs. 3).—The author records the finding of this canine tapeworm in an infant.

## FOODS—HUMAN NUTRITION.

Studies on the digestibility of the grain sorghums, C. F. LANGWORTHY and A. D. HOLMES (*U. S. Dept. Agr. Bul.* 470 (1916), pp. 31).—This bulletin reports data regarding the digestibility of the grain sorghums, dwarf kafir corn,

feterita, dwarf milo maize, and kaoliang, obtained by feeding these to seven normal young men. The grains were ground to a meal and eaten either in the form of bread, with a basal ration of potato, apple sauce, butter, and sugar, or as a mush, with a basal ration of apple sauce, butter, sugar, and sirup. For comparison similar experiments were made with breads prepared from corn and wheat meals. The results of these experiments may be summarized briefly as follows:

When the kafir corn was eaten in the form of hard bread, 58 per cent of its protein was digested. This value may be high owing to the large proportion of milk protein in the diet. When eaten in the form of a softer bread the average digestibility of the protein of the dwarf kafir corn was 51 per cent, of the feterita 51 per cent, of the dwarf milo maize 40 per cent, and of the kaoliang 20 per cent. When eaten as a mush the percentage digestibility of the protein of the dwarf kafir corn was 48 per cent, of the feterita 48 per cent, of the dwarf milo maize 34 per cent, and of the kaoliang 4 per cent. No attempt was made to estimate the digestibility of the fat as supplied by cereals since it was present in very small quantity.

The carbohydrates of the experimental ration and of the sorghums alone were found to be very completely utilized.

"Considering the grain only, as distinguished from the ration as a whole, the average value for the kafir corn (hard) bread was 98 per cent, for softer dwarf kafir corn bread 96 per cent, and for dwarf kafir corn mush 96 per cent. In the case of carbohydrates supplied by feterita, the average values were 97 per cent for the bread and 99 per cent for the mush; with dwarf milo maize 96 per cent for the bread and 98 per cent for the mush; and for kaoliang 96 per cent for both bread and mush."

The corn and wheat proteins were found to be somewhat less thoroughly digested than is usually the case, this being due probably to the coarseness of the meals used. The average digestibility of the corn bread protein was 60 per cent and of the coarse wheat bread protein 77 per cent. As the experiments with all the grains were conducted under uniform conditions it is concluded that the protein of the grain sorghums is less digestible than that contained in either corn or wheat.

These experiments and information available regarding the preparation of the sorghums for the table indicate that these grains are valuable as human food. In cooking, care must be taken that they absorb a sufficient quantity of water so that the particles of meal which are characteristically hard may be well softened. The flavor of the grain sorghums is generally agreeable. Although their protein is less completely assimilated than that of corn or wheat, they are, with the exception of kaoliang, fairly good sources of this food constituent. In addition, they are a good source of carbohydrate, which they furnish in a form very completely available to the body.

**On the digestibility of bread.—II, Salivary digestion of erythro-dextrin in vitro,** J. C. BLAKE (*Jour. Amer. Chem. Soc.*, 39 (1917), No. 2, pp. 315-320, figs. 2).—Further data are reported upon one phase of the experiments reported in the first article of this series (E. S. R., 35, p. 468), namely, the effect of moderate variations in concentration upon the activity of the amylases studied. The following conclusions are drawn:

"The digestion of erythro-dextrin by ptyalin is a monomolecular reaction. The optimum temperature for this digestion is 51° C. (91.8° F.). The temperature coefficient is relatively small at the ordinary temperature, being about the same as that of chemical reactions in general. The enzyme is destroyed at 65°. The digestion becomes disproportionately slow when the ratio of substrate to enzyme becomes very large. This ratio is constant for different

concentrations, and probably represents a compound formed by the union of the enzym and the substrate preliminary to hydrolysis. The retarding influence of maltose is shown to be relatively small and to vary directly as its concentration. The relatively slow digestion of achroödextrin is again pointed out, and a preliminary redetermination of its specific rotation made."

Food supply orders [milling of flour] (*Bd. Trade Jour. [London]*, 95 (1916), No. 1043, pp. 570, 571).—Note is made of the percentages of flour which must be obtained from wheats of various qualities, according to an order of the British Government.

Government control over flour, W. JAGO (*Nature [London]*, 98 (1916), No. 2457, pp. 250, 251).—This article discusses the flour-milling order noted above, especially with regard to the quality of the bread and flour produced and the question of increasing the percentage of flour obtainable from the wheat.

Flour standards, W. JAGO (*Nature [London]*, 98 (1917), No. 2464, p. 390).—In increasing beyond a certain point the percentage of flour from a given amount of wheat the author advocates the addition of flour derived from barley, maize, rice, or oats, rather than the addition of wheat offal. While the flours from barley and the other cereals mentioned show an absence of gluten, they do not contain the proteolytic and starch-converting enzymes present in the whiter portion of the wheat offal, which acts diversely on the gluten and starch of the flour.

Trichinæ in pork and nematodes in butterfish in their relation to the implied warranty in the sale of articles of food, C. W. STILES (*Jour. Amer. Med. Assoc.*, 68 (1917), No. 9, pp. 685-687).—The author states that from the standpoint of the zoologist the term "diseased" in the sense of the food laws should be interpreted differently from its academic meaning, and that the terms "diseased meat" and "meat from diseased animals" really mean meat which is likely to produce disease when eaten by human beings. In discussing the question of implied warranty on the part of the food vendor, on the basis of this interpretation of the term diseased meat, he maintains that there is justification for the vendor of live shellfish, chickens, fish, or other raw foods to assume that the purchaser of these foods is under an implied guaranty to see that they will be properly handled and prepared for reception into the stomach before they are served as food. In discussing the sale of raw pork attention is called to the facts that the absence of live trichinæ in fresh pork can not be guaranteed by any known practical method of inspection and that if the pork is properly cooked any trichinæ present are killed and hence can not produce disease.

With reference to the nematodes which were found in some samples of butterfish, the author states that these fish should not be considered as diseased in the above sense, since the encysted worms were present chiefly on the entrails and if properly dressed and cooked the fish would not be liable to produce disease in man, although from the standpoint of the fish themselves they were undoubtedly diseased.

[Analyses of] baking powder, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 360 (1917), pp. 25*).—Analytical data are given regarding 213 samples of commercial baking powders.

Annual report 1916 Food and Drug Department State of Tennessee, H. L. ESKEW (*Ann. Rpt. Food and Drug Dept. Tenn., 1916, pp. 22*).—The activities of the department during the year 1916 consisted in the inspection of hotels, the testing of weights and measures, and the examination of 1,358 samples of miscellaneous foods, drugs, and beverages.

State laws and regulations pertaining to public health adopted during the year 1915 (*Pub. Health Rpts. [U. S.], Reprint 338 (1915-16), pp. XIX+612*).—Many of the laws included in this compilation relate to foodstuffs.

Twentieth annual convention of the Association of American Dairy, Food, and Drug Officials, held at Detroit, Michigan (*Proc. Assoc. Amer. Dairy, Food, and Drug Officials, 20 (1916), pp. 239, fig. 1*).—The proceedings are reported of the meetings held at Detroit, Mich., August 7-11, 1916.

The following papers were among those read: Malnutrition through Errors in the Combination of Foods, by E. V. McCollum; Demonstration of Simple Steam Sterilizer for Farm and Dairy Utensils, by G. B. Taylor; Inspection of Grocery Stores and Markets, by H. C. Smith; Skim Milk as a Human Food, by J. P. Street; Laboratory Control of Food Industry, by H. E. Barnard; Contribution to Knowledge of Chemical Composition of Fruit Extracts, by W. S. Long; Relation of Composition to Quality of Cheese, by J. N. Currie; Inspection of Canned Foods, by W. D. Bigelow; and Sanitation in Food Control, by G. G. Frary.

The reports of committees are included. As a part of the report of the committee to assemble current literature on the subject of nutritional disorders, the result of so-called devitalized foods, there is included an extensive bibliography of nutritional deficiency diseases, prepared by S. J. Crumbine.

Food values—what they are, and how to calculate them, MARGARET MCKILLOP (*London: George Routledge & Sons, Ltd.; New York: E. P. Dutton & Co., 1916, pp. VIII+136*).—This book brings together a great deal of information regarding the value of different kinds of foods in the diet and the nutritive requirements of men, women, and children. Tables are given which show the chemical composition and fuel value of a large number of different foods. A chapter is devoted to the use of these tables in determining the proportion of different food constituents furnished by made dishes, daily diets, and weekly menus, and another to miscellaneous calculations.

Food values, R. HARCOURT (*Ontario Dept. Agr. Bul. 245 (1916), pp. 14*).—This bulletin contains data regarding the economic selection of different foods and some information on bread making.

Food supplies and prices in war time, with special reference to imports (*Jour. Bd. Agr. [London], 23 (1917, No. 10, pp. 955-965)*).—A compilation of statistical data regarding the supplies of meat, dairy products, cereals, fruits, and vegetables.

War food societies (*Jour. Bd. Agr. [London], 23 (1917), No. 10, pp. 965-969*).—Information is given regarding the activities of different societies having for their object the increase and economic use of the food supply.

[Diet in the Kansas State Penitentiary], J. E. CATON in (*Official Report by State Accountant Relating to the State Penitentiary. Topeka, Kans.: State, 1916, pp. 11-14*).—This report contains several recommendations made by E. H. S. Bailey and others by L. A. Congdon regarding the food furnished the inmates of the prison.

Some interrelations between diet, growth, and the chemical composition of the body, L. B. MENDEL and SARAH E. JUDSON (*Proc. Nat. Acad. Sci., 2 (1916), No. 12, pp. 692-694*).—The results are reported of 88 analyses of the entire body of the white mouse at different stages of growth.

It was found that the ash content of mice growing normally on an artificial food mixture of milk powder, casein, starch, salts, and butter fat was uniformly higher at the corresponding stages of growth than the ash content of mice fed a ration of mixed grain, dog bread, and small amounts of milk. When the diet contained an abundance of fat but not enough protein to maintain normal growth the fat content of the animal was found to be greater than

when the food contained adequate protein with the same proportion of fat. By underfeeding gain in weight was arrested and constant weight maintained for 30 and 60 days. Comparison of the composition of these stunted mice with that of mice growing normally showed that "the proportion of fat in the stunted animal is about the same as in the normal mouse of the same weight (but younger), while the percentage of water in the fat-free substance corresponds to the water content of a normal mouse of the same age (but heavier)." The ash content of the stunted mice was greater than that of the normal mice of the same weight.

Retardation of growth by reduction of protein or salts in the food or by substitution of gliadin for other proteins affected the ash content of the animal in the same way as did underfeeding. Young mice maintained for a time at constant weight when given sufficient food again grew at a greatly accelerated rate, which enabled them to overtake control mice which had grown uninterruptedly. The ash content, however, did not increase at the same rate and the development of the skeleton did not, in the active growth which accompanied refeeding, keep pace with the rapid gain in body weight, so that in a few days the normal relation was almost reestablished.

**Ammonia and amino acids in the stomach and intestinal content with exclusively vegetable diet.** G. AGNOLETTI (*Arch. Farmacol. Sper. e Sci. Aff.*, 22 (1916), No. 7, pp. 261-273).—From observations on animals (horses and asses) the following conclusions were drawn:

A part of the nitrogenous portion of the soluble fraction of the stomach content not found as total nitrogen was present in the form of ammonia, and a much greater part in the form of amino acids. The quantities of ammonia nitrogen and nitrogen titratable as formol found in the intestine exceeded the quantities found in the stomach. In general with each group of animals receiving the same food (hay, Indian corn, and oats) a high percentage of amino acids in the intestinal content corresponded to a high percentage of amino acids in the soluble portion of the stomach content.

The influence of milk and carbohydrate feeding on the character of the intestinal flora.—IV, Diet versus bacterial implantation, T. G. HULL and L. RETTGER (*Jour. Bact.*, 2 (1917), No. 1, pp. 47-71).—The experiments here reported were made with laboratory animals (white rats) and are a continuation of earlier experiments (E. S. R., 33, p. 460). These were supplemented also by experiments with other laboratory animals and men. The following conclusions are drawn in part from the data presented:

*Bacillus acidophilus* (Moro) and *B. bifidus* (Tissier) are common inhabitants of the intestinal tract of the white rat and of man, sometimes being present in small numbers and at other times excluding all other forms, at least for short periods. "The typical flora of infants which subsist on mothers' milk is a good illustration of the extent to which one intestinal organism (*B. bifidus*) may dominate and even supplant all other types. The most important factor in determining the character of the flora is the diet.

"Lactose, milk, and mixed grains (wheat, oats, etc.) are specific articles of diet which exert an influence on the intestinal bacteria. Lactose, when fed in sufficient quantities (2 or 3 gm. daily), brings about a complete transformation of the flora of white rats within two or three days; milk requires a longer time, and does not bring about a complete change. Milk and lactose together form the most practical and effective diet, at least for man. Grain feeds tend to increase the number of aciduric bacteria, but their influence is comparatively small.

"Milk undoubtedly owes its beneficial action to the lactose, which constitutes almost half of the solid matter present. The explanation of this action must lie in the fact that the lactose is absorbed slowly from the intestine. On several

occasions it has been found in the feces of rats that had been supplied with it as a part of their diet. The raw grains are also probably acted upon slowly, or at least some of the intermediate carbohydrate products are not immediately absorbed. Bread, on the other hand, which contains cooked starch, does not foster the development of the aciduric bacteria, because it is digested quickly, and no available sugar remains in the intestine long enough to be attacked and utilized by this group of bacteria. . . .

"Meat or other high protein diet increases the indol-producing bacteria and other organisms of the so-called 'putrefactive' type, like *B. coli* and *B. welchii*; cornstarch appears to foster the amylolytic group of intestinal organisms, while in a few experiments grain feed seemed to favor the development of what appeared to be fusiform bacilli.

"The reaction of the intestine remained independent of the character of the intestinal flora. While the acidity of the intestinal contents varied in different rats, it was not increased during the course of lactose feeding experiments. The acidity was highest in the duodenum, as a rule, and lowest at the ileo-cecal valve.

The marked influence of a high lactose diet upon the intestinal flora of man, which was demonstrated in these experiments, has been confirmed by other investigators working with typhoid patients, who found that eating milk sugar (250 to 300 gm. daily) brought about a marked change in the intestinal flora where the initial flora had been of a distinctly putrefactive type. The authors state that in both the earlier and present work they were unable to establish *B. bulgaricus* in the intestine of white rats even for short periods of time, although the bacilli were fed in large numbers. These results are in harmony with those of other investigators.

A bibliography of cited literature is appended.

**Experimental studies of the intestinal flora, W. R. Sisson** (*Amer. Jour. Diseases Children, 13 (1917), No. 2, pp. 117-127*).—Experiments are reported in which was studied the effect of various foods commonly used in infant feeding on the bacterial flora of the intestinal tract. The observations were made on infants and laboratory animals (puppies). The bacterial flora of the puppies fed on cow's milk was found to be essentially the same as that of infants on a similar diet. The following conclusions were drawn from the experiments with puppies:

"In puppies the types of organisms occurring at the duodenum, ileum, cecum, and rectum are in all instances similar. One can not speak of a characteristic local flora occurring in these regions.

"Feedings to puppies of cow's milk mixtures with high percentage of sucrose or lactose does not cause characteristic changes in the intestinal flora at any level, even when a diarrhea is produced.

"Starvation of 24 hours renders a relative amicrobism of the small intestine."

**The influence of fresh and autoclaved cows' milk on the development of neuritis in animals, R. B. Gibson and ISABELO CONCEPCION** (*Philippine Jour. Sci. Sect. B, 11 (1916), No. 3, pp. 119-133, pls. 2, figs. 2*).—Feeding experiments are reported with laboratory animals (fowls, pigs, and dogs). These were carried out to determine whether or not antineuritic substances were present in milk and to what extent these would be affected by autoclaving the milk for two hours at 125° C.

The results obtained showed the antineuritic vitamins to be present in milk in slight amounts only, and that the continued feeding of either fresh or autoclaved milk without suitable additions to the diet induced symptoms of beriberi. The authors state that the antineuritic powers of milk are so slight that in infant feeding the diet should be extended as soon as possible, and that

the young of healthy mothers are probably born with a reserve supply of the so-called vitamin substances sufficient to maintain them in good nutritive condition until the time when they begin to eat other foodstuffs. No evidence was obtained in these experiments that autoclaving the milk for two hours at 125° C. in any way affected its nutritive value.

### ANIMAL PRODUCTION.

The feeding of animals, W. H. JORDAN (*New York: The Macmillan Co., 1917, rev. ed., pp. XVII+473, pls. 8, figs. 17*).—This is a new and revised edition of the work previously noted (E. S. R., 13, p. 880). The recent advances in the subject of animal feeding with respect to growth and maintenance under various conditions, together with the results of recent investigations on growth-promoting substances, have been included.

The relative value of certain proteins and protein concentrates as supplements to corn gluten, T. B. OSBORNE, L. B. MENDEL, ET AL. (*Jour. Biol. Chem., 29 (1917), No. 1, pp. 69-92, fig. 1*).—In this paper the authors present data regarding the growth of laboratory animals (rats) which throw light upon the relative nutritive value of a number of proteins and protein concentrates when used to supplement corn gluten in an otherwise adequate ration. The substances studied included casein, lactalbumin, edestin, cottonseed protein, cottonseed flour, soy-bean flour, "milk albumin," beef tissue, fish-meat meal, corn-oil cake, "vegetable-albumin flour," brewers' grains, distillers' grains, pea meal, and peanut meal.

The results of the experiments indicate that "such food mixtures of approximately the same nitrogen and calorific content vary greatly in their efficiency for promoting growth, in accordance with both the character and the proportion of the protein supplement employed. The efficiency of these supplements presumably depends essentially upon their relative content of lysin and tryptophan; for the addition of these amino acids, either as such or in the form of proteins yielding them, renders corn gluten suitable for growth.

"Of the various proteins employed to supplement the inefficient corn gluten, lactalbumin is by far the most effective. Satisfactory growth is produced with smaller quantities of this protein than of any of the others recorded. The samples of brewers' grains, distillers' grains, and 'vegetable-albumin flour' used were the least efficient supplements tested, presumably because of their low content of lysin.

"It is evident that the small additions of the more efficient proteins actually supplement the corn gluten instead of themselves furnishing all of the protein used for growth, because equivalent amounts of these proteins alone in a similar ration are incapable of inducing a comparable degree of growth. Small amounts of a superior protein are often just as efficient for growth as larger amounts of a less adequate protein."

The authors state that the plan of feeding here described affords a practical method for studying accurately the comparative nutritive value of the nitrogenous components of commercial feeding stuffs.

[Bacteriological examination of feeding stuffs] (*Dept. Landb., Nijv. en Handel [Netherlands], Verstag. en Meded. Dir. Landb., No. 5 (1916), pp. 12, 13*).—The bacteriological examination of feeding stuffs as a control of soundness and freshness is noted. Normal samples were found to contain from 5,000,000 to 10,000,000 organisms per gram, while spoiled samples showed as high a content as 50,000,000 bacteria per gram of sample. The acidity of linseed cake was found to run parallel with the number of micro-organisms and also the degree of rancidity.

**Inspection of commercial feed stuffs**, P. H. SMITH ET AL. (*Massachusetts Sta. Control Ser. Bul. 5 (1916)*, pp. 4-69).—Brief comments are made upon the results of feeding stuffs inspection in the State during the year ended September 1, 1916, and the results are given of the analyses of cottonseed meal, linseed meal, corn oil cake, coconut meal, peanut meal, gluten meal, gluten feed, distillers' dried grains, malt sprouts, brewers' dried grains, yeast and vinegar grains, red dog flour, wheat middlings, wheat bran, corn meal, corn bran, hominy meal, dried beet pulp, buckwheat bran, meat scrap, beef scrap, digester tankage, bone meal, fish scrap, fish meal, clover meal, alfalfa meal, and mixed and proprietary feeds.

A brief article on the net weights of feeding stuffs is appended, together with tabulated wholesale cost data of feeding stuffs for the year.

**Condimental stock foods and proprietary remedies**, W. G. GAESSLER (*Iowa Sta. Circ. 31 (1916)*, pp. 2-4).—Advice is given against the indiscriminate purchase and use of condimental stock foods and tonics.

**The breeding of animals**, F. B. MUMFORD (*New York: The Macmillan Co., 1917*, pp. XVII+310, pls. 32, figs. 17).—In this manual for students and breeders of animals the author discusses the principles of genetics as they apply to the practice of animal breeding in accordance with the conclusions of biologists. Emphasis is placed upon those principles and practices that belong peculiarly to the province of the animal breeder, while not neglecting the lessons and illustrations to be drawn from the field of plant breeding.

**The maintenance of breeding ewes of mutton and wool sheep**, B. O. SEVERSON (*Pennsylvania Sta. Bul. 144 (1916)*, pp. 3-20, figs. 6).—This bulletin is a summary of experiments upon the maintenance of breeding Shropshire and Delaine-Merino ewes begun at the station in 1911. The results secured during 1911-1913 have already been noted (E. S. R., 34, p. 171; 35, p. 565).

During the winter periods 1913 to 1916 the sheep used were a few of the ewes remaining from the former tests and some of their offspring. The Shropshire pens, lots 1 and 2, consisted of 8 ewes each in the winter of 1913-14 and 10 ewes each in the winters of 1914-15 and 1915-16. The Delaine-Merino pens, lots 3 and 4, consisted of 6 ewes each in the winters of 1913-14 and 1914-15 and 8 ewes each in the winter of 1915-16. During the three winters 1913 to 1916 the different lots received the same grain mixture as the corresponding lots during the earlier period except that no cottonseed meal was fed. The roughage consisted of alfalfa hay for lots 1 and 3 and corn silage and alfalfa hay for lots 2 and 4. For lots 2 and 4 the alfalfa hay was limited to 2 lbs. per head daily for lot 2 and to 1.75 lbs. for lot 4 in 1915-16, and the silage to 2 lbs. per ewe daily in 1913-14. In 1914-15 the grain mixture was not fed previous to lambing and only to ewes that yeaned. During the summers the ewes were alternated on two pastures every two weeks. They flocked together without any grain except for a few weeks prior to and during the breeding season.

The average annual cost of maintenance of these ewes from December, 1913, to May, 1916, including interest, depreciation, and mortality risk, with alfalfa hay at \$15 per ton, was \$9 for lot 1, \$7.59 for lot 2, \$8.29 for lot 3, and \$7 for lot 4. The average percentages of lambs by the ewes that yeaned were 195, 163, 115, and 126, and the percentages of lambs raised by ewes that yeaned were 110, 95, 95, and 100, respectively, for the four lots during the three years. The average weight of the lambs at weaning time for the four lots was 58.78, 59, 57.6, and 53.1 pounds, respectively. The average weight of fleece per ewe was 8.56 lbs. for lot 1, 7.66 for lot 2, 12.3 for lot 3, and 11.13 for lot 4. The average loss in weight per ewe during the three winter periods was 23.72 lbs. for lot 1, 19.87 for lot 2, 9.38 for lot 3, and 6.63 for lot 4. During the

summers of 1914 and 1915 the average gain in weight per ewe was 37.2 lbs. for lot 1, 33.52 for lot 2, 23.91 for lot 3, and 26.45 for lot 4.

It is concluded that "alfalfa hay at \$15 per ton is too expensive as a sole roughage for breeding ewes of these types. Alfalfa hay with a grain mixture of 0.25 lb. per ewe daily produces vigorous lambs, results in a greater growth of wool, and stimulates a greater milk flow than a ration of corn silage, alfalfa hay, and grain. When alfalfa hay is fed without grain to breeding ewes prior to lambing the lambs are weak at birth and the ewes give less milk than with grain. . . . A ration of alfalfa hay, corn silage, and a limited grain mixture is more economical by 15.6 per cent than alfalfa as a sole roughage, and is satisfactory for pregnant ewes.

"Ewes fed no grain prior to lambing produced stronger lambs and gave more milk [when silage supplemented alfalfa hay]. Except for the 1915 crop of lambs, when no grain was fed prior to lambing, the lambs of lots 1 and 3, fed alfalfa hay as a sole roughage, carried a higher condition of flesh and made more rapid gains than those in lots 2 and 4, respectively. . . . A greater amount of manure was produced by ewes fed alfalfa hay as a sole roughage. . . .

"The lambs produced by the Delaine-Merinos were heavier at birth than the Shropshire lambs, due to a small proportion of twins. The Delaine-Merino lambs were hardier at birth and the ewes required less care than did the Shropshires. The cost of maintenance per ewe decreases with the increase in number of ewes in a flock to a unit of at least 40 ewes. . . . Shropshire lambs are worth from 50 to 75 cts. more per 100 lbs. live weight than Delaine-Merino lambs. . . .

"A high percentage of good market lambs is the most important factor in profitable sheep raising. Exercise and care of breeding ewes are as important as feeds in increasing the percentage of lambs. . . . Feed racks which prevent seed and chaff from getting into the fleece increase the value of wool from 1 to 2 cts. per pound."

Of the average income that was realized from the four lots during the last three years of the experiments when 100 per cent lambs were raised, 65.6 per cent was for mutton and 34.4 per cent for wool.

Poultry breeding and management, J. DRYDEN (*New York: Orange Judd Co., 1917, pp. XIV+402, figs. 188*).—This book, which contains a large number of illustrations and is of special interest to students of poultry culture and to poultry farmers, treats of the subject under the following chapter headings: Historical aspect, evolution of modern fowl, modern development of the industry, classification of breeds, origin and description of breeds, principles of poultry breeding, problem of higher fecundity, systems of poultry farming, housing of poultry, kind of house to build, fundamentals of feeding, common poultry foods, methods of feeding, methods of hatching chickens, artificial brooding, marketing eggs and poultry, and diseases and parasites of fowls.

The behavior of chickens fed rations restricted to the cereal grains, E. B. HART, J. G. HALPIN, and E. V. McCOLLUM (*Jour. Biol. Chem., 29 (1917), No. 1, pp. 57-67, pl. 1*).—The experiments reported in this paper include observations extending through two years.

It was found that chickens started at half the normal weight could make slow growth, maintain themselves, and produce fertile eggs on rations limited to corn meal, gluten feed, and calcium carbonate, or wheat meal, wheat gluten, and calcium carbonate. These results are in marked contrast to those with swine or rats where these rations resulted in loss of weight and cessation of oestrus, and with wheat to a condition resembling polyneuritis.

"It is apparent that the mineral requirements at least, and possibly the requirements for the other normal nutritive factors, are not the same for chickens

as they are for mammals. Further, the chicken's ability to tolerate, without disaster and without modification of the ration, the toxic material of wheat speaks for a metabolism distinct from that of swine or rats.

"Where half-grown chickens were used there was no important improvement in the rates of growth or egg-lying capacity by supplementing the grains with either salts, casein, or butter fat, or a combination of the three, as contrasted with the results secured with the grain, grain protein concentrate, and calcium carbonate ration. The protein level in all cases was approximately 12 per cent. On all of these rations the number of eggs produced, although fertile, was limited. This fact, at variance with the best results of practice where animal protein concentrates have proved of great value as supplements to cereal grains for a large egg production, would suggest that either the higher plane—20 to 25 per cent—of protein intake of superior quality secured in practice by the use of the animal protein concentrates (meat scraps, milk, etc.) explains these differences, or else the latter contribute certain factors necessary for large egg production which the cereal grain concentrates or casein fail to carry. The matter needs further investigation."

Winter egg production, A. R. LEE (*U. S. Dept. Agr., Office Sec. Circ. 71 (1917), pp. 4*).—Suggestions are given for the stimulation of winter egg production in pullets and to some extent in hens by proper methods of feeding, housing, and handling.

### DAIRY FARMING—DAIRYING.

The influence of the plane of nutrition of the cow upon the composition and properties of milk and butter fat: The influence of underfeeding, C. H. ECKLES and L. S. PALMER (*Missouri Sta. Research Bul. 25 (1916), pp. 3-107, figs. 15*).—The investigations reported in this bulletin are in continuation of those already noted (*E. S. R., 35, p. 774*).

In these experiments three pure-bred Jersey, one pure-bred Holstein, one pure-bred dairy Shorthorn, and two pure-bred Ayrshire cows were used. Sixteen experimental feeding periods were carried out with these cows, six of which were begun immediately after parturition, four within 30 days after parturition, and six somewhat later in the lactation period. In addition five experimental periods with the above cows, involving the reduction of a super-normal plane of nutrition, and seven experimental periods with cows other than the above, involving physiological underfeeding, are discussed.

The three types of underfeeding considered are those in which (1) the plane of nutrition of the cow is reduced to subnormal, (2) the plane of nutrition is reduced but not to subnormal, and (3) the cow is unable for physiological reasons to consume sufficient food to support the milk flow immediately after parturition. Of the factors which influence the effects of underfeeding on the composition and properties of milk and butter attention is given to (1) the stage of lactation period of the cow, (2) the degree of underfeeding, (3) the character of the ration, (4) the state of flesh of the cow, (5) the plane of nutrition of the animal previous to underfeeding, and (6) the length of the underfeeding period.

Data connected with the experiments are tabulated and shown graphically in the appendix. The following conclusions are drawn:

"A subnormal plane of nutrition causes a cow in lactation to lose more or less weight, depending on the state of flesh of the animal, the degree of underfeeding, and the length of time the animal is underfed.

"The effects of a subnormal plane of nutrition on the milk flow depend upon the stage of the lactation period at the time of underfeeding. Cows subjected

to a subnormal plane of nutrition immediately after parturition maintain their milk flow at a nearly constant level under the most adverse conditions. In one experiment a constant flow was maintained for 30 days with sufficient food for body maintenance only. A decline in milk flow accompanies even moderate underfeeding when the lactation period has reached a certain stage. The exact point when this occurs was not determined in the experiments. The explanation of this difference in the effect on the milk flow is believed by the authors to rest on the conception that the milk flow of the cow is stimulated by two factors, (1) chemical, (2) nervous. The former is more or less independent of the food supply and predominates for a period of time after parturition. The latter is almost entirely dependent on the food supply and predominates, or replaces the chemical stimulus, after the lactation period has attained a certain stage.

"Physiological underfeeding and reduction in the plane of nutrition from a high to a normal plane is invariably accompanied by a marked increase in the percentage of fat in the milk, especially when the cow has a surplus store of fat on her body. In the case of physiological underfeeding there is almost invariably an actual increase in the yield of milk fat, as well as in the percentage in the milk [E. S. R., 27, p. 280]. The effects of an induced subnormal plane of nutrition on the percentage and yield of fat in the milk are variable, an increased fat percentage sometimes resulting, in other cases there being no change, while in others an actual decrease in the percentage of fat results. The factors that appear to cause these variations are the state of flesh of the animal, the degree of underfeeding, and the season of the year in which the experiment is conducted.

"A subnormal plane of nutrition at times affects the percentage of protein in the milk. In some of the experiments conducted there was a decline in the percentage of casein, while in others the total protein only was affected. In the latter cases the percentage of ash in the milk also decreased. None of the types of underfeeding influenced the percentage of lactose in the milk.

"All types of underfeeding have marked effects on the physical and chemical constants of the butter fat, which are characterized by a decline in the Reichert-Meissl number and saponification value and an increase in the iodine value. Three types of results were noted with respect to the effects on the melting point of the butter fat, (1) increase in melting point, (2) stationary melting point, and (3) decrease in melting point. These differences are explained by the facts that in the group of experiments with increased melting point the decline in the volatile fatty acids was relatively greater than the increase in the oleic acid. In the group of experiments with constant melting point, the changes in the two kinds of fat constituents offset each other with respect to their effects on the melting point. In the group in which the melting point declined, the increase in oleic acid was relatively much greater than the decline of the volatile fatty acids.

"The proportion of volatile fatty acids in butter fat has a much greater influence on the melting point than the proportion of oleic acid. This was strikingly shown in several of the underfeeding experiments, in which marked changes in the melting point of the fat occurred with variations in the Reichert-Meissl number in spite of the fact that the iodine value remained abnormally high throughout the experiment.

"The more important factors influencing the effects of underfeeding on the fat constants are the character of the ration, the degree of underfeeding, and the length of the underfeeding period. Corn silage and other feeds which increase the volatile fatty acid content of butter fat, affect the degree of abnormality of the fat constants accompanying underfeeding, but not their amount of

change. The effects of underfeeding on the fat constants appear to reach a limit with a subnormal plane of nutrition of about —40 per cent. Long continued underfeeding results in more or less recovery of the fat constants from the most abnormal values, but the recovery is never complete.

"The increase in the percentage of milk fat and the changes in the character of the fat which accompany underfeeding are not satisfactorily explained by the hypothesis that underfeeding causes a transfer of tissue fat to the mammary glands. Blood fat analyses made during the height of physiological underfeeding in the case of two cows failed to show any increase in the amount of fat carried by the blood stream in comparison with normal conditions in the same animals.

"As a basis for the explanation of the effects of underfeeding on the percentage of fat in milk and on the composition of the fat, the hypothesis is advanced that the synthesis of milk fat in normal amount and its synthesis with normal composition are independent physiological functions. The production of the normal amount of milk fat is controlled by the activity of the lipases and other enzymes which accelerate this synthetic reaction in the mammary gland, and is influenced greatly by changes in the general metabolic activity of the body, particularly by the changes that affect the fat metabolism. By this hypothesis it is possible to explain the normal variations in the percentage of fat in the milk, the variations which occur with extreme weather conditions (which have a particularly strong influence on the general energy metabolism of the animal), as well as the variations in the effects of underfeeding on the percentage of fat in the milk, especially those that appear to be related to the fatness or thinness of the cow. The synthesis of milk fat of normal composition is controlled by variations in the amount and kind of material presented to the milk glands by the blood stream, from which the normal constituents of milk fat are formed, particularly those which especially characterize the milk fat, namely, the volatile fatty acids. A further extension of this phase of the hypothesis is limited by the lack of knowledge as to which constituents of the blood are utilized for the formation of normal milk fat.

"The effects of underfeeding on the composition and properties of milk and butter fat show the importance of controlling this factor in feeding experiments involving the effects of specific feeds on the composition of milk and butter. The effects of underfeeding must be taken into account in the interpretation of all data involving variations in the composition of milk and butter fat due to specific conditions of the cow, specific environments of the cow, changes in the feed of the cow, or to feeds of specific character.

"The variations in the composition and properties of milk and butter fat with underfeeding of the cow may have an important bearing on the use of such milk for human food, particularly as food for infants. Lack of data on this phase of the problem, however, makes it impossible to state how much bearing the results have in this connection."

Further studies of the relation of the quality of proteins to milk production, E. B. HART, G. C. HUMPHREY, and A. A. SCHAAL (*Jour. Biol. Chem.*, 26 (1916), No. 2, pp. 457-471, figs. 4).—In continuation of previous studies (E. S. R., 33, p. 275), data are here presented on the comparative value for milk production of the proteins of gluten feed, linseed meal, distillers' grains, casein, and skim milk powder. Three pure-bred Holsteins of large milking capacity and not with calf were used in the experiments. Each animal was placed on one ration for a 4-week period with immediate change to another concentrate, thus involving each individual cow in from 16 to 20 weeks of observation. Each ration contained approximately 2 lbs. of digestible protein of which 50 per cent.

came from the particular concentrate under investigation. The total protein intake constituted about 10 per cent of the dry matter of the ration and the nutritive ratio was about 1:8.

With a daily production of from 40 to 45 lbs. of milk containing from 10 to 12 per cent of total solids, a negative nitrogen balance persisted throughout the experiments, this negative balance being very much larger with the gluten feed ration than with any of the other concentrates. Only during the period of skim milk powder feeding was one of the animals storing nitrogen. "In spite of this long negative balance milk secretion continued at the expense of catabolizing tissue. The total yield and total solids of the milk declined slightly after two months of continuous negative nitrogen balance.

"There was a marked difference in the utilization of the concentrates: Gluten feed showed a percentage efficiency of 45, oil meal 61, distillers' grains 60, casein 59, and skim milk powder 60. These data represent the efficiency in the mixture used.

"Possible errors in calculation may arise from the supplementing effect of the catabolizing tissue, thereby raising the figures above their true value, but nevertheless they do have comparative worth. . . . These studies furnish additional evidence that the nutritive ratio or plane of protein intake for milk production may vary according to the nature of the concentrates and basal ration used."

The influence of the ration on the composition of the urine of dairy cows, T. E. KEITT (*South Carolina Sta. Rpt. 1916, pp. 37-48*).—In these investigations, three lots of 1 aged cow and 1 heifer each were fed from June 19, 1913, to March 18, 1915. Lot 1 received a balanced ration of linseed meal, corn meal, and wheat bran; lot 2 cottonseed meal and linseed meal (1:4); and lot 3 cottonseed meal. The rations of all the lots were supplemented with pasturage and corn silage when the pasturage was scant.

The urine of each of the animals was secured for various 24-hour periods throughout the experiment and the amounts voided per diem, together with the urea content, are tabulated. Analytical data are also tabulated for the urine of each cow for each of these 24-hour periods, regarding the specific gravity, acidity, chlorids, phosphates, albumin, acetone, sugar, indican, total solids, ash, free ammonia, nitrogen, lime, and color.

In the case of the cow in lot 1 there seemed to be a direct relation between the color of the urine and its specific gravity—the higher the specific gravity the deeper the color. A short time before calving the specific gravity of the urine ran very low and at this time all of the constituents were quite low, probably due to large dilution. There seemed to be no definite relation between the total ash content and the content of lime and of phosphorus. The total solids varied in a general way with the specific gravity.

The phosphorus content of the urine of the heifer in this lot was lower than that of the cow, but the contents of nitrogen, urea, free ammonia, and lime were higher. The contents of nitrogen, urea, and free ammonia ran lower in these two animals than in those fed the highly nitrogenous feed, indicating that a highly nitrogenous feed throws more work on the urinary system of the animal and that the excess of nitrogen above the balanced ration is metabolized.

With lot 2 the relation between color and specific gravity did not hold. There was not much lowering of the specific gravity of the urine previous to calving in this lot. After two months of the experiment had elapsed there was a noticeable increase in the urea content of the urine of this lot, this being true irrespective of the fluctuations in volume of the urine voided. This was true of all animals receiving high protein rations, but it did not hold good for the animals on the balanced ration.

The carrying of a fetus seemed to have some bearing on the content of lime and phosphorus in the urine, this being especially noticeable in the aged cows. Immediately after calving the urine of the cow in lot 1 greatly increased in lime and phosphorus content. Later the lime and phosphorus contents became lower. With the cow in lot 2 there was a great increase in phosphorus content immediately after calving, but the lime content remained low. Beginning a month after this cow was bred again there was a marked decline in phosphorus and lime. The contents of lime and phosphorus were greatly increased after the second calving.

The content of both lime and phosphorus in the urine of the cow in lot 3 was comparatively low during pregnancy, and there was a noticeable increase in the lime content after calving. The phosphorus content of the urine of the heifer in lot 1 increased after the birth of her first calf, and the lime content after the second calf. With the heifer in lot 2 the lime content increased after calving. The phosphorus content had been high and continued so.

Report for 1915 of the united dairy experiment farm at Hoorn (*Verlag Ver. Exploit. Proefzuivelboerderij Hoorn, 1915, pp. 103, pls. 2, figs. 7*).—This contains a financial report of the institution, together with results of an experimental test of two milking machines, and studies to determine whether the fat in cheese exercises an influence on the ripening, the proteolytic power of lactic acid cocci, the production of cleavage products of lactose by lactic acid bacteria (*Streptococcus lacticus*) in milk and whey, the normal gas formation in cheese, the Duclaux method for determining fatty acids, and the "cracking" of Edam cheese.

Milk yield tests in cows, J. KÄPPELI (*Milchw. Zentbl., 45 (1916), No. 2, pp. 17-24*).—Tabular experimental data of the milk yielded by cows at the Berner-Liebefeld experiment station during the years 1899-1914, together with data relative to the feed received, are submitted and discussed. It is concluded in general that for determining the total milk yield for any period of lactation weighing the milk once every two weeks is satisfactory and yields average results which are accurate enough for all practical purposes.

Certificate-of-record dairy cows.—A world's record, W. M. SINGLETON (*Jour. Agr. [New Zeal.], 13 (1916), No. 4, pp. 293, 294, fig. 1*).—The Jersey heifer, Mere, commenced milking at the age of 1 year and 346 days, and produced in 1 year 12,164 lbs. of milk containing 663.64 lbs. of fat. This is said to be a world's record for the production of milk fat for animals of this age.

Regulations adopted by the Argentine Rural Society for registering milk records of dairy cows (*An. Soc. Rural Argentina, 51 (1916), No. 1, pp. 74-76; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 856-858*).—This gives the text of the resolutions adopted by the Argentine Rural Society for the registering of milk records of dairy cows which are recognized as suitable for forming milking strains.

An experiment with milk veins, R. R. GRAVES (*Hoar's Dairyman, 52 (1916), No. 20, pp. 687, 717, figs. 6*).—In the experiment here briefly reported the milk veins of two cows were ligated in order to determine whether the posterior mammary veins would carry all the blood from the udder.

With one of the cows, which had been in lactation about 18 months, there was no shrinkage in milk flow following the tying of one vein, and only slight shrinkage following the tying of the other vein a week later. In the case of the other cow, which had been in milk a little over two months and had a daily milk production of about 44 lbs., the milk flow was only slightly lowered, due to the tying of the milk veins.

Postmortem examinations of these cows showed that the posterior mammary veins were about as large as the anterior veins. The author suggests that

undue emphasis is attached to the milk veins in the score cards of the various breeds of dairy cattle.

The influence of heating on creaming in milk, R. BURRI (*Milchw. Zentbl.*, 45 (1916), No. 3, pp. 33-39).—Experimental data are submitted which show that a preliminary heating of the milk below its boiling point markedly shortens the time for complete creaming. Pasteurization at 61° C. (141.8° F.) for 30 minutes produces a very rapid and complete separation of the cream. Heating at higher temperatures increases the creaming time.

The practical significance of the results in regard to the determination of the correct temperature for pasteurization is indicated.

The behavior of *Streptococcus lacticus* on heating milk at 60 to 63° C. (modern pasteurization), H. WEIGMANN, A. WOLFF, MARG. TRENSCH, and M. STEFFEN (*Centbl. Bakt. [etc.]*, 2. Abt., 45 (1916), No. 1-5, pp. 63-107).—The results of the investigation show that after heating milk for 30 minutes at from 60 to 63° C. (140 to 145.4° F.) the lactic acid bacteria are present, in general, in a much larger proportion to the remaining organisms than in the raw milk. The same was found on heating the milk for only 10 or 20 minutes.

Milk drawn in the stable was found to contain a proportionately larger number (about double) of the acid bacteria than milk drawn in the field, while the number of acid organisms which survived pasteurization was from four to five times as great in the stable milk.

In spite of the larger proportion of acid bacteria in the pasteurized milk than in the raw milk the time of souring was considerably longer than in the raw milk. From experimental data in this connection it is concluded that the acid bacteria in the pasteurized milk were attenuated both with respect to reproduction and fermentation. The creaming of the pasteurized milk was found to be much more rapid and also more complete than in the raw samples.

The detailed bacteriological data are submitted in tabular form and discussed in some detail.

See also a previous note by Ayers and Johnson, jr. (*E. S. R.*, 29, p. 73).

Testing milk and cream, M. R. TOLSTRUP and M. MORTENSEN (*Iowa Sta. Circ.* 32 (1916), pp. 2-8, figs. 14).—Brief directions are given for testing whole milk, cream, and skim milk for fat by the Babcock method, together with some common causes for poor tests and reasons for variations in cream tests.

Why cream tests vary, H. A. RUEHE (*Illinois Sta. Circ.* 192 (1917), pp. 2).—This circular gives in a concise form information as to the cause of variations in cream testing.

Caring for cream on the farm, H. A. RUEHE (*Illinois Sta. Circ.* 190 (1917), pp. 2, fig. 1).—Brief suggestions are given.

Care of the cream separator, H. A. RUEHE (*Illinois Sta. Circ.* 191 (1917), pp. 2).—Suggestions deemed helpful to separator operators are offered.

[Chemical comparison of two fermented milk products], A. SANNA (*Staz. Sper. Agr. Ital.*, 49 (1916), No. 2, pp. 73-88).—The Sardinian fermented milk product, "micuratu" or "gioddu," is compared with the Egyptian product "leben" or "laben raieb."

## VETERINARY MEDICINE.

The principles of pathologic histology, F. B. MALLORY (*Philadelphia and London: W. B. Saunders Co.*, 1914, pp. 677, figs. 497; rev. in *Jour. Bact.*, 1 (1916), No. 5, pp. 550, 551).—This book, which treats of pathology from the morphologic point of view, consists of two parts, the first relating to general pathologic histology (pp. 17-410) and the second to special pathologic histology (pp. 411-662). The review is by F. P. Gay.

Veterinary materia medica and therapeutics, K. WINSLOW (*New York: William R. Jenkins Co., 1916. 7. ed., rev., pp. [14]+781*).—This is the seventh revised edition of the work previously noted (E. S. R., 20, p. 1183). Much new data relating to therapeutics have been added, together with a number of medicinal agents not previously included and a complete section on poisons and antidotes. Spinal anesthesia is considered in detail for the first time.

Live stock sanitary laws of the State of Arkansas, R. M. Gow (*Arkansas Sta. Bul. 126 (1916), pp. 14*).—This consists of the text of the state laws, the regulations of the board of control of the station regarding them, notes on the laws and regulations, etc.

Report of the nineteenth annual meeting of the United States Live Stock Sanitary Association (*Rpt. U. S. Live Stock Sanit. Assoc., 19 (1915), pp. 194, figs. 2*).—The papers presented at the annual meeting of the association, held at Chicago, December 2 and 3, 1915, include the following: A Disease Resembling "Forage Poisoning" in Horses and Mules Wherein Oat Hay Incorporated the Primary Factor, by R. Graham, L. R. Himmelberger, and R. L. Pontius (pp. 22-42), previously noted (E. S. R., 36, p. 580); The Advisability of State-wide Compulsory Pasteurization, by W. B. Barney (pp. 42-45); Summary of Investigation on Immunization Against Anthrax, by A. Eichhorn (pp. 45-56); Infectious Pneumonia of Cattle (Hemorrhagic Septicemia), by A. T. Kinsley (pp. 56-59); Hog-cholera Investigations, by M. Dorset (pp. 59-74); Official Control of the Production and Distribution of Commercial and State Serum, by C. J. Sihler (pp. 74-78); Tick Eradication, by C. A. Cary (pp. 79-81); Advantages of Closer Cooperation Between Bureau of Animal Industry and State Officials in the Control of Contagious and Infectious Diseases, by C. Vrooman (pp. 81-83); The Use of Concrete in Sanitary Farm Equipment, by N. K. Wilson (p. 84); Cooperation with Bureau of Animal Industry in the Control and Eradication of Contagious and Infectious Diseases, by O. H. Eliason (pp. 85-89); Inspection of Live Stock for Interstate Movement, by D. F. Luckey (pp. 89-96); Sanitation in Connection with Transportation of Live Stock, by A. J. Davies (pp. 96-101); Disinfection of Local Stockyards and Farm Premises, by F. A. Bolser (pp. 101-103); and Effective Quarantine as a Factor in Controlling Foot-and-mouth Disease, by U. G. Houck (pp. 103-112).

The following papers presented before the conference on foot-and-mouth disease at Chicago, November 29-30, 1915, and previously noted (E. S. R., 35, p. 74), are included in the appendix: An Ideal State Law for Cooperation Between State and Federal Authorities in Work of Eradicating Contagious Animal Diseases, by C. J. Marshall (pp. 143-147); What General and What Specific Rules Should Be Observed in Fixing the Periods and Duration of the Different Forms of Quarantine Against Foot-and-mouth Disease, by V. A. Moore (pp. 147-153); Economic Effect on Business Men as well as Farmers of Temporary Outbreaks and of Permanent Presence of Live Stock Disease, by A. J. Glover (pp. 153-159); and Quarantine Zones or Units, by J. I. Gibson (pp. 159-161).

Report of the New York State Veterinary College for the year 1913-14 (*Rpt. N. Y. State Vet. Col., 1913-14, pp. 310, pls. 15*).—The following papers are included in this report: The Diagnosis of Open Cases of Tuberculosis, by D. H. Udall and R. R. Birch (pp. 55-105); A Study of Hog-cholera Transmission, by R. R. Birch (pp. 106-114); Contagious Abortion of Cattle (pp. 115-162); Suggestions for the Repression of Abortion, Sterility, and Mammitis in Cows and of White Scours in Calves (pp. 163-174), and The Cause, Prevention, and Treatment of Retained Placenta in the Cow (pp. 175-188), by W. L. Williams; An Improved Technique for the Handling of Fistulous

Withers, by W. L. Williams and J. N. Frost (pp. 189-199); An Outbreak of Septicæmia Hemorrhagica Among Cattle in New York State (pp. 200-206) (E. S. R., 34, p. 478), and A Review of the Principal Methods Used to Standardize Bacterins (Bacterial Vaccines) with Special Reference to the Use of the Hemocytometer (pp. 207-219), by C. P. Fitch; The Determination of Anthrax by Means of the Thermo-precipitation Reaction (pp. 220-254), Tuberculosis in Pheasants (pp. 255-260) (E. S. R., 34, p. 386), and A Cysto-adenoma in a Fowl (pp. 261-268), by E. M. Pickens; and The Location of the Accessible Lymph Glands in Cattle with Reference to Physical Diagnosis, by E. Sunderville (pp. 269-276).

Report of the New York State Veterinary College at Cornell University for the year 1914-15 (*Rpt. N. Y. State Vet. Col., 1914-15, pp. 224, pls. 24*).—The following papers are included in this report: Preliminary Report on the Recognition of Swamp Fever or Infectious Anemia in New York State, by D. H. Udall and C. P. Fitch (pp. 50-62) (E. S. R., 34, p. 280); Researches upon Contagious Abortion of Cattle, by W. L. Williams (pp. 63-101); Report on the Conglutination Test with Special Reference to the Diagnosis of Glanders, by C. P. Fitch (pp. 102-115) (E. S. R., 34, p. 781); Instructions in Selecting, Packing, and Shipping Tissues for Laboratory Examination, by E. M. Pickens (pp. 116-128); A Preliminary Report on Verminous Bronchitis in Dogs, by H. J. Milks (pp. 129-135); Uncinariasis in Dogs, W. E. Muldoon (pp. 136-141); The Structural Changes that Occur in Certain Nonspecific Inflammations of Joints, by S. A. Goldberg (pp. 142-181); The Limitations of Tuberculin in Detecting Tuberculous Infected Animals, by V. A. Moore (pp. 182-189); Physiologic Relations—Poultry, by P. A. Fish (pp. 190-204); and Lobar Pneumonia, So-called, in Domesticated Animals, by S. H. Burnett (pp. 205-220).

Proceedings of the Wisconsin Veterinary Medical Association (*Proc. Wis. Vet. Med. Assoc., 1 (1916), pp. 161, figs. 5*).—A report of the first annual meeting of the association, held at Madison, January 18-20, 1916.

Annual report of proceedings under the diseases of animals acts, the markets and fairs (weighing of cattle) acts, etc., for the year 1915 (*Bd. Agr. and Fisheries [London], [Vet. Dept.], Ann. Rpt. Proc., 1915, pp. 44*).—This consists mainly of the report of the assistant secretary, animals division, A. W. Anstruther, on the work during the year with hog cholera and the recurrence of foot-and-mouth disease. Statistical tables relating to the number of animals in Great Britain, number exported from Ireland to Great Britain, number imported from and exported to foreign countries, and diseases among animals in Great Britain are appended.

Annual report on the civil veterinary department, United Provinces, for the year ended March 31, 1916, E. W. OLIVER (*Ann. Rpt. Civ. Vet. Dept. United Prov., 1916, pp. II+22+2*).—This is the usual annual report (E. S. R., 34, p. 777).

New apparatus for the veterinary laboratory, N. MORI (*Ann. Staz. Sper. Malattie Infet. Bestiame, R. Ist. Incoragg. Napoli, 2 (1914), No. 2, pp. 209-234, figs. 14*).—An apparatus for keeping liquids hot during filtration, an apparatus for sterilizing surgical instruments with steam, a container for use in sterilizing and conserving rubber stoppers used for serum vials, a new model serum vial, a culture flask for growing micro-organisms in either solid or liquid media, a support for the serum container used during the filling of a syringe, a device for holding animals (rat or mouse) during inoculation, and a support for surgical instruments during autopsies are described in detail.

The preparation of culture media from whole blood, R. A. KELSER (*Jour. Bact., 1 (1916), No. 6, pp. 615-617*).—The author describes in detail the preparation of a medium from whole fresh beef blood. In a comparative test with

beef bouillon, in which various types of organisms, including streptococci, staphylococci, *Bacillus typhi*, *B. diphtheriæ*, *B. anthracis*, *B. tuberculosis*, *B. abortus*, *B. mallei*, etc., fungi, and saccharomyces, were used, in all cases where a noticeable difference of growth was observed it was in favor of the blood media.

The medium can be used in preparing various modifications and on account of its low cost and ease of preparation it is strongly recommended.

Methods of raising a low arterial pressure, W. M. BAYLISS (*Proc. Roy. Soc. [London]*, Ser. B, 89 (1916), No. B 617, pp. 380-393).—"When the arterial pressure is low from loss of blood, it can not be brought back, except to a certain degree, by the injection of saline solution in volume equal to that of the blood lost. But if the viscosity of such solutions is raised to that of the blood, a return to normal height is possible. The effect of saline injections is also much less lasting than that of solutions containing gum or gelatin. The difference in this case is due to the osmotic pressure of the colloids, by which loss of water by the kidneys and to the tissues is prevented. Solutions containing gum do not produce edema in artificial perfusion of organs.

"When the fall of blood pressure is due to peripheral vasodilatation, gum or gelatin solutions, although more effective than pure saline, produce a much less permanent rise than in cases of loss of blood. No signs of heart failure could be detected and the cause of the fall of the raised pressure to its original height is still obscure. The combination of a small dose of barium chlorid, as recommended by Langley,<sup>1</sup> with a moderate amount of gum solution was found to be the most satisfactory method in such cases and no diminution of vasomotor excitability resulted.

"The view that fall of arterial pressure produces peripheral vasoconstriction by means of nervous channels, and that rise of arterial pressure produces vasodilatation was confirmed by artificial perfusion of a limb."

Studies in anaphylaxis, XVIII, XIX, R. WEIL (*Jour. Immunol.*, 2 (1916), No. 1, pp. 95-124, figs. 5).—Two studies are reported, continuing previous work (E. S. R., 34, p. 778).

XVIII. *The mechanism of delayed shock* (pp. 95-108).—Experimental data submitted show that there is, in actively sensitized guinea pigs in which the circulating blood has been largely replaced by normal blood, a delayed reaction on the intraperitoneal injection of antigen. Circulating antibody is not a factor in the production of delayed shock, since the simultaneous injection of antibody intravenously and of antigen intraperitoneally does not induce anaphylactic symptoms. "The isolated uterus effectively reproduces the picture of delayed shock if the antigen is very gradually added from a burette.

"The factors in the mechanism of acute and of delayed shock are identical, namely, the reaction of cellular antibody with freshly introduced antigen. In the case of acute shock the reaction is immediate, owing to the sudden introduction of antigen, which is, as a rule, accomplished by the intravascular route. In the case of delayed shock the reaction is delayed, owing to the cumulative effect of the gradual absorption of antigen, as from the peritoneal cavity."

It is indicated that the gradual mode of reaction of the cells may possibly explain some of the symptoms of infectious diseases.

XIX. *Simultaneous injections of antigen and antiserum.*—*The anaphylatoxin theory of anaphylaxis* (pp. 109-124).—Characteristic anaphylactic symptoms have been produced in guinea pigs, in exceptional cases only, by the simultaneous but separate injection of antigen and antibody intravenously. In rab-

<sup>1</sup> *Jour. Physiol.*, 45 (1912), No. 4, pp. 239-260.

bits characteristic anaphylactic symptoms have never been induced by separate simultaneous injections. "The injection of previously prepared mixtures of antigen and antibody frequently produces violent anaphylactiform symptoms in guinea pigs and in rabbits. This is due to certain chemical alterations ('anaphylatoxins') which may also be produced by incubating normal serum in vitro with a great variety of substances, such as agar, starch, heterologous serum, etc. The injection of these latter substances intravenously has never been shown to produce anaphylactic symptoms. It appears, therefore, that serum in the test tube reacts quite differently from plasma of the circulating blood.

"The interaction of antigen and of antibody in the circulating blood does not give rise to toxic substances (anaphylatoxins) and does not produce anaphylactic symptoms. Anaphylaxis, by which is meant the reaction of the previously treated animal to a fresh injection of antigen, is always and invariably mediated by cellular antibody, and by that alone."

**Streptothrix in broncho-pneumonia of rats similar to that in rat bite fever, RUTH TUNNICLIFF** (*Jour. Infect. Diseases*, 19 (1916), No. 6, pp. 767-772, pls. 3).— "A streptothrix similar to *Streptothrix muris-ratti*, isolated from the blood of patients with rat bite fever, has been observed in smears and isolated in pure culture from the lungs of rats with broncho-pneumonia. An increase in opsonins and agglutinins for this organism has been found in infected rats. Acute lesions have been produced in the lungs of rats inoculated intraperitoneally with cultures of this organism."

**The influence of the climatic and tellurical factors on the distribution and spread of certain animal diseases, with special reference to the conditions occurring in South Africa, D. KEHOE** (*So. African Jour. Sci.*, 12 (1916), No. 11, pp. 474-501).—This discussion relates particularly to tick and insect borne diseases and those caused by helminths.

**Tick bite in stock and its treatment, S. T. D. SYMONS** (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 11, p. 767).—In the coastal areas of Australia the scrub tick (*Ixodes holocyclus*) is troublesome to young stock and in many cases fatal to foals, calves, pigs, dogs, and cats, particularly in the autumn and early spring. Although not producing death in the case of adult horses and cattle, its bite causes considerable irritation and pain. When attached the ticks may be destroyed by dropping turpentine or kerosene upon them. A laxative should be administered to the affected animals at once and followed by a stimulant.

**Anthrax, J. A. LANAHAN** (*N. Y. State Indus. Com. Spec. Bul.* 79 (1916), pp. 22, pls. 3, fig. 1).—This reports upon the occurrence of anthrax in New York State, the causes of the outbreaks, and methods of control and eradication.

**The treatment of glanders with salvarsan, especially suspicious horses, and its influence on the production of antibodies, H. MIESSNER and W. LANGE** (*Deut. Tierärztl. Wchnschr.*, 24 (1916), No. 14, pp. 127-130; *abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 6, p. 849).—The results of the treatment of eight animals in a test of the value of salvarsan and neosalvarsan are reported in detail. Animals which manifested no apparent symptoms of glanders, but whose blood indicated its presence, were used. Blood examinations were made before and after the injection in order to observe the effect of the drug on the formation of antibodies.

In general the authors conclude that it is impossible to cure glanders with either salvarsan or neosalvarsan.

No very conclusive results were obtained by the blood examinations or by the serological tests. In using the agglutination test, however, a reduction of antibodies in the sick animals was observed shortly after the injection, with a con-

siderable increase a short time afterwards. The use of salvarsan or neosalvarsan might thus be of value in detecting the presence of the disease in horses.

The preparation of an antiglanders serum, P. CRIMI (*Ann. Staz. Sper. Malattie Infet. Bestiame, R. Ist. Incoragg. Napoli, 2 (1914), No. 2, pp. 237-255*).—The experiments reported demonstrate that an excellent serum against glanders can be produced by inoculation of the hog, sheep, horse, or cow.

The serum produced was obtained by the subcutaneous injection of a virulent broth culture of *Bacillus mallei*. The injections were started with an initial dose of 10 cc., and for each succeeding injection double the amount previously used was injected until 6 liters of culture were used. The injections were made at periods ranging from 7 to 15 days apart.

The injection of the antiserum obtained into a pigeon which had previously been inoculated with a virulent culture of *B. mallei* showed it to possess marked prophylactic and curative properties. Used in doses of 0.25 cc. the serum produced the recovery of a pigeon 48 hours after the first injection of 0.1 cc. of a virulent culture, while the control bird was killed in 60 hours. The serum prolonged the time of death of a pigeon which had received a 0.1 cc. dose of virulent culture the previous day.

The serum used solely as a prophylactic in doses of 0.1 cc. conferred an immunity on pigeons which lasted several months.

The serum taken from an animal four months after the last injection of the virulent culture was, as might be expected, almost completely deprived of its immunizing properties.

Various methods for determining the trypanocidal activity of substances in vitro and their relation to the chemotherapy of experimental trypanosomiasis, J. A. KOLMER, J. F. SCHAMBERG, and G. D. RAIZISS (*Jour. Infect. Diseases, 20 (1917), No. 1, pp. 10-27*).—"Trypanocidal tests in vitro have been found of distinct value in chemotherapeutic researches in experimental trypanosomiasis. Substances exerting a profound trypanocidal activity in vitro are likely to prove trypanocidal in vivo, provided the drug is sufficiently non-toxic to be administered in adequate dosage. With the combined in-vitro-vivo method . . . it has been found possible to detect the trypanocidal activity of new compounds which were without effect in vivo in amounts but slightly less than the sublethal dose."

Salvarsan has been shown to possess a high trypanocidal activity in vitro. A trypanocidal activity by mercurials which is not apparent in vivo tests has been demonstrated by in vitro methods. In the combined in-vitro-vivo method described, equal parts of varying dilutions of the material are mixed with blood trypanosome emulsion and kept at 37 to 40° C., when the whole or a part is injected intraperitoneally into white rats to determine the degree of trypanocidal activity. As a part of the drug is injected its action is both in vitro and in vivo. Care must be exercised, however, against the administration of lethal doses of the drug.

The numeric relationship of infection to the chemotherapy of experimental trypanosomiasis, J. A. KOLMER, J. F. SCHAMBERG, and G. D. RAIZISS (*Jour. Infect. Diseases, 20 (1917), No. 1, pp. 35-44*).—Experiments reported demonstrate that in the chemotherapy of trypanosomiasis an important relation exists between the number of trypanosomes injected into the test animal and the trypanocidal activity on the part of the drug. This relationship is particularly evident with respect to the amount of drug necessary to effect complete sterilization.

The importance of this relationship to the results of chemotherapeutic experiments, particularly in comparative tests, is indicated.

The tubercle bacillus in the sputum and other body fluids, H. BIERRY (*Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 21, pp. 618-621*).—Directions and brief notes on the isolation of tubercle bacilli from the blood, pleural exudate, and spinal fluid are submitted.

Summary of the conclusions reached regarding contagious abortion, V. A. MOORE (*Amer. Jour. Vet. Med., 12 (1917), No. 2, pp. 78-80*).—A discussion before the annual meeting of the U. S. Live Stock Sanitary Association, held at Chicago, in December, 1916.

The cause of the "spewing sickness" of sheep, C. D. MARSH (*U. S. Dept. Agr., Bur. Anim. Indus. [Pub.], (1916), pp. 4, fig. 1*).—Heavy losses have occurred on the sheep ranges in the Wasatch Mountains in Utah from what is known locally as "spewing sickness." The description of symptoms given by sheepmen has corresponded very closely with those known to result from poisoning by the death camas (*Zygadenus venenosus*). Investigations conducted in 1915 have, however, shown quite conclusively that the spewing sickness of that summer was not caused by death camas but was due to another plant, namely, *Dugaldia hoopesii*, known locally as "sneezeweed."

The present preliminary paper has been prepared with a view to furnishing sheepmen with information to enable them to recognize the plant and be on their guard against it. It is said to grow at elevations of from 7,000 to 10,500 ft., ranging from Wyoming in the North to Arizona and New Mexico in the South, and as far west as California. It is a rank-growing plant, and in some localities has largely taken possession of extensive areas on the range.

"The marked symptoms of poisoning by *Dugaldia* are depression, weakness, salivation, nausea accompanied with vomiting, and a weak, irregular pulse. Diarrhea is common, and bloating is a prominent symptom in sheep poisoned on the range. The effect on the pulse is especially characteristic, and it is evident that the toxic principle in large doses has a specific effect on the heart." While all parts of the plant are poisonous, experiments seem to indicate that the flowers are somewhat more so than the leaves. It is thought probable that cases of acute poisoning are rare, but it is known that sheep may be poisoned by eating from 2.5 to 3 lbs. in a single day, although most cases of range poisoning are the result of feeding extending over several days or perhaps two or three weeks. Thus far no medicinal remedy can be recommended, and the main reliance must be placed upon prevention.

Annual reports of the camel specialist for the years 1914-15 and 1915-16, H. E. CROSS (*Ann. Rpts. Camel Specialist [Punjab], 1914-15, pp. 21; 1915-16, pp. 27, figs. 11*).—The usual reports (*E. S. R., 32, p. 184*) dealing with the diseases of camels in the Punjab.

Biological investigations on hog cholera in southern Italy, N. MORI (*Ann. Staz. Sper. Malattie Infet. Bestiame, R. Ist. Incoragg. Napoli, 2 (1914), No. 2, pp. 191-206, figs. 2*).—A disease similar to the disease prevalent in hogs was produced in young healthy pigs by the subcutaneous injection of the diluted serum of the sick hogs which had previously been passed through a Berkefeld filter. Similar results were obtained by ingestion of the virus or by subjecting the animals to exposure to diseased hogs. Animals which recovered from an infection produced by subcutaneous injection of the filtered virus were found to be immune to a possible infection by ingestion of the virus. The virus which originally produced the disease in healthy animals later produced antibodies in animals which had recovered from an infection.

It is indicated that the disease which exists in southern Italy is probably the same as that recognized in America as hog cholera.

The destruction of trichinæ by cold, E. LECLAINCHE (*Rev. Gén. Méd. Vét., 25 (1916), No. 293, pp. 198-206; abs. in Jour. Compar. Path. and Ther., 29*

(1916), No. 2, pp. 183-186).—This is a review of the literature relating to the effect of cold upon trichinae, including the work of Ransom, previously noted (E. S. R., 34, p. 680).

The occurrence of the giant nematode on the liver of a dog, W. A. RILEY and W. L. CHANDLER (*Cornell Vet.*, 6 (1916), No. 4, pp. 209-212, pls. 2).—The authors record a case of parasitism of the liver of a South Carolina dog by *Dictyophyme renale*, together with the pathological conditions which it induced.

Botulism, a cause of limber-neck in chickens, E. C. DICKSON (*Jour. Amer. Vet. Med. Assoc.*, 50 (1917), No. 5, pp. 612, 613).—Investigations of outbreaks of botulism due to the consumption of home-canned corn, string beans, apricots, etc., which resulted in the death of human beings as well as of chickens fed on remnants of the materials indicate that botulism may be a cause of limber-neck in chickens. Anaerobic bacilli, which had all the morphological and cultural characteristics of *Bacillus botulinus*, were obtained from the gizzards of several of the fowls. The fact that the *B. botulinus* toxin may be formed in certain vegetables and fruits without the addition of animal protein may explain the occurrence of this disease of domestic fowl under conditions in which access to spoiled meats can be excluded.

### RURAL ENGINEERING.

The effect of sudden enlargement upon the flow of water in pipes, T. J. RODHOUSE (*Cornell Civ. Engin.*, 25 (1916), No. 2, pp. 49-61, figs. 3).—Experiments on the effect of the flow of water of sudden enlargement of 1 and 1.5 in. pipe to a pipe whose diameter is 2.096 in., and a study of the action of the Pitot tube under disturbed conditions, are reported. The following conclusions are drawn:

"The Pitot tube measures with a fair degree of accuracy, always within 2 or 3 per cent and more frequently within 1 per cent, the velocities of flow in a pipe where the resultant motion of the water throughout the entire cross section at the point where the tube is inserted is a forward motion, and where the distribution of velocities is symmetrical about the axis of the pipe. The Pitot tube is a means by which eddies or whirls caused by obstructions in the pipe may be detected, but it will not measure with any degree of accuracy the discharge of a pipe when inserted in the immediate region of such eddies.

"The rating coefficient of discharge of the Pitot tube for normal conditions can not be applied in the case of abnormal conditions produced by sudden enlargement where eddies exist, but immediately below the region of eddies the rating coefficient of discharge may be applied with a fair degree of accuracy. The eddies produced by sudden enlargement of section extend for the short distance of only about 2 or 3 diameters below the enlargement. The disturbance caused by sudden enlargement of section produces abnormal conditions in the distribution of velocities which continue down the pipe for a distance of about 35 diameters.

"The ratio of the mean velocity to the velocity at the center,  $\frac{V_m}{V_c}$ , increases in value, in the case of sudden enlargement, from a minimum near the point of enlargement to a maximum at a point about 11 diameters downstream, after which it begins to gradually decrease, approaching the value of the ratio for flow in straight pipe at a distance of 35 diameters below enlargement. The loss of head due to sudden enlargement may be expressed by the equation,  $H_b = K \left( \frac{A_2}{A_1} - 1 \right) \frac{V_1^2}{2g}$  a constant times the theoretical loss by Borda's formula, and in making the observations for the total loss due to this disturbance, a

distance of at least 35 diameters of the downstream section, below the enlargement must be included. The value of the coefficient  $K$  is very nearly the same in the two cases of enlargement investigated, and is approximately 0.97.

"The Pitot tube reversed, i. e., the impact point turned downstream, gives a negative pressure head which, reduced to velocity, negative, gives a value whose ratio with the velocity in the upstream direction is fairly constant for any given form of tube. But the relative values of the downstream readings to the upstream readings for different forms of tubes vary greatly. The maximum negative pressure or suction action at the impact point of the Pitot tube occurs when the direction of the axis of the opening is approximately perpendicular to the direction of flow."

Value of Kutter's " $n$ " for metal flumes (*Reclam. Rec. [U. S.]*, 8 (1917), No. 1, p. 37).—Tests made on the North Platte and Uncompahgre irrigation projects to determine the value of the coefficient  $n$  in Kutter's formula for metal flumes are reported. "The results indicate that 0.012 is a fair average value for  $n$  in flumes with smooth interior, and that 0.013 may be considered amply safe for design."

Holding power of nails (*Engin. Rec.*, 75 (1917), No. 2, p. 71).—From experiments on the holding power of 16d. and 20d. nails in a direction perpendicular to the length of the nail in which 2 by 12 in. yellow pine planks were nailed to fir sills and sheared off, a safe loading of 210 lbs. for 16d. and 250 lbs. for 20d. nails was assumed for use in the heel plates of the wooden flumes on the West Okanogan Irrigation Project.

Friction of bronze on bronze (*Reclam. Rec. [U. S.]*, 8 (1917), No. 1, p. 36).—Experiments on the coefficient of friction of bronze on bronze to be used in estimating the power required in the operating mechanism for large high-pressure sluice gates are reported. The tests were made on gates at the Pathfinder, Arrowrock, and Elephant Butte dams, all of which are provided with cast bronze bearing surfaces and are operated by oil pressure on pistons moving in cylinders mounted on the gate bodies. The results are given in the following table:

*Gate tests.*

Dam.	Size of gates (larger dimension vertical).	Head on center of gates.	Average time of opening	Average time of closing.	Friction coefficient.			
					Average for open- ing stroke	Maximum for opening stroke.	Average for closing stroke.	Maximum for closing stroke.
	<i>Feet.</i>	<i>Feet.</i>	<i>Minutes.</i>	<i>Minutes.</i>				
Pathfinder.....	4.42×7.5	12	16.0	14.0	0.420	0.440	0.290	0.310
Arrowrock.....	5×5	48.5-54.8	10.0	11.0	.310	.420	.290	.340
Elephant Butte..	3.92×5	107.3	5.2	4.2	.336	.383	.254	.268

Report on irrigation surveys and inspections, 1915-16 (*Dept. Int. Canada, Irrig. Branch Rpt. 1915-16, pp. 86, pls. 4*).—This includes the reports of the Superintendent and Commissioner of Irrigation and of the chief field inspector; a summary report on duty of water and irrigation crop reports; and reports on bench marks, on the Cypress Hills, Western Maple Creek, and Calgary irrigation districts, on international waterways, and on the Lethbridge Northern Irrigation Project, for 1915-16.

State Rivers and Water Supply Commission [of Victoria], eleventh annual report, 1915-16 (*Victoria Rivers and Water Supply Com. Ann. Rpt., 11 (1916), pp. 39, pl. 1, fig. 1*).—A statement of the work and expenditures of the commission for the financial year 1915-16, and estimates for 1916-17.

The specific gravity of nonhomogeneous aggregates, P. HUBBARD and F. H. JACKSON, JR. (*Amer. Soc. Testing Materials Proc.*, 16 (1916), pt. 2, pp. 378-402, figs. 6; *abs. in Cement Era*, 14 (1916), No. 9, pp. 40-43, figs. 6).—The object of this investigation was to study methods in common use, or those which gave promise of being most satisfactory, for the determination of apparent and true specific gravity of mineral aggregates, with a view to ascertaining if possible what method is most generally applicable to all classes of materials and also the most accurate. The methods studied were as follows: (1) The ordinary displacement method as conducted by the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture, (2) the Chapman method for single specimens, (3) the Goldbeck method, (4) the Hubbard-Jackson method, (5) the Chapman wire-basket method, (6) the Le Chatelier method for fine aggregates, and (7) the Jackson method for fine aggregates. Descriptions of these tests in detail, together with illustrations, are given. Sixteen samples of crushed rock, three samples of crushed slag, a sample of gravel, and three samples of sand were used in the investigation. The following conclusions were drawn:

"(1) In the case of rock and slag an appreciable variation may exist between apparent specific gravity and true specific gravity, depending upon the absorption of the material. (2) It is impracticable by any of the methods studied to determine the apparent specific gravity of samples composed of fragments smaller than 0.5 in. in diameter. (3) Methods employing single test specimens are not safe to use for determining the specific gravity of nonhomogeneous aggregates, even when the average results of three apparently representative samples are taken. (4) In the case of nonhomogeneous aggregates consisting of fragments of not less than 0.5 in. in diameter, all of the methods employing 1,000-gm. samples are satisfactory and can ordinarily be depended upon to give check results by different operators working upon the same sample to within one in the third significant figure. (5) When determining the specific gravity of extremely nonhomogeneous aggregates, it is recommended that the average of not less than three tests, made upon different 1,000-gm. samples, be reported. (6) When it is desired to obtain as nearly as possible the apparent specific gravity of aggregates consisting of a mixture of coarse and fine particles, it has appeared advisable to separate a weighed sample of the material by means of a 0.5-in. screen, and to make an apparent-specific-gravity determination upon not less than 1,000-gm. of the coarse fraction and a true-specific-gravity determination upon not less than 50-gm. of the finer fraction. The approximate apparent specific gravity of the whole sample may then be calculated from the results obtained."

A new form of specifications for concrete aggregates, C. M. CHAPMAN (*Amer. Soc. Testing Materials Proc.*, 16 (1916), pt. 2, pp. 180-193).—This paper proposes that instead of specifying that concrete aggregates, particularly sand, be of a certain fixed minimum standard of quality, the specifications be made to read in effect as follows: The materials used shall be of such quality and shall be used in such proportions as to produce a concrete which shall show a compressive strength of 2,500 (or 2,000 or 1,500) lbs. per square inch at the age of 28 days under standard test. A brief outline of the manner in which this form of specification is utilized in practice is also given.

A method of making wear tests of concrete, D. A. ABRAMS (*Amer. Soc. Testing Materials Proc.*, 16 (1916), pt. 2, pp. 194-208, figs. 6; *abs. in Engin. and Contract.*, 46 (1916), No. 5, pp. 102, 103, figs. 4).—A brief review of tests used for determining the wearing resistance of concrete and concrete aggregates, especially for use in the wearing surface of roads, is given, and a method is

described for conducting wear tests on concrete blocks 8 in. square and 5 in. thick by means of the Talbot-Jones rattler.

The strength of clamped splices in concrete reinforcement bars, E. L. LASIER (*Amer. Soc. Testing Materials Proc.*, 16 (1916), pt. 2, pp. 209-238, figs. 12; *abs. in Engin. and Contract.*, 45 (1916), No. 26, pp. 578, 579, fig. 1; *Engin. Rec.*, 74 (1916), No. 2, pp. 48, 49).—"U-bolt clamped splices of both 17- and 21-in. lengths of splice were tested to determine the load at first slip and the maximum load the splice would resist. Three different classes of splices were thus tested, (1) lap splices not embedded in concrete, (2) butt splices not embedded in concrete, and (3) lap splices embedded in concrete. The reinforcement steel in all cases consisted of 1-in. square cold twisted bars.

"The loads necessary to produce first slip had a range of from 7,000 to 50,000 lbs. The maximum loads which the splices withstood varied from 23,000 to 69,000 lbs. The ratios of load at first slip to yield point of bar for clamped splices not embedded in concrete varied from 12 to 21 per cent, and for splices embedded in concrete from 53 to 83 per cent. Ratios of maximum load to tensile strength of bar ranged from 31 to 61 per cent for unembedded splices, and from 79 to 95 per cent for embedded splices. The conclusions which may be drawn from the tests are as follows:

"The 4-in. difference in lengths of lap tested, of one bar upon the other, apparently does not affect the rigidity or strength of the splice. The clamped lap splices not embedded in concrete sustain, on the average, a slightly greater load before first slip, and a larger maximum load, than the clamped butt splices. Splices consisting of two bars of opposite twist probably sustain a greater load before first slip, and a larger maximum load, than do splices in which the bars have like twist.

"When U-bolt clamped lap splices (of the type, size, and lengths reported upon) are embedded in masses of concrete similar to those of the test specimens, the splices may be expected to withstand a stress before first slip equal to at least one-half the yield point stress of the continuous reinforcement bar. Also, the maximum strength of such splices is probably equal to at least three-fourths of the tensile strength of the bar. When U-bolt clamped lap splices (of the type and lengths reported upon) are embedded in relatively large masses of concrete, it is reasonable to suppose that first slip would not occur, or the splice would not completely fail, before the yield point or tensile strength, respectively, of the reinforcement steel had been reached; for in such cases the splices would undoubtedly fail only by the pulling out of the bars along the grooves (either through untwisting or through direct shear), and not by splitting of the surrounding concrete. In either case, unlike the results in the tests, the clamps would remain embedded in the concrete, unless the concrete prism directly compressed by the area of the upper or lower clamps were pulled out also, a condition which is not in the least likely to occur with a relatively large mass of concrete. Hence for purposes of design, it is probable that such U-bolt clamped lap splices, embedded in concrete under conditions ordinarily obtaining in actual practice, could safely withstand a unit load equal to the allowable unit stress in the steel reinforcement bars."

An apparatus for determining soil pressures, A. T. GOLDBECK and E. B. SMITH (*Amer. Soc. Testing Materials Proc.*, 16 (1916), pt. 2, pp. 309-319, figs. 3; *abs. in Engin. News*, 76 (1916), No. 8, p. 339, fig. 1; *Engin. Rec.*, 74 (1916), No. 2, p. 48, fig. 1).—This paper describes an apparatus for measuring the pressure under earth fill or against walls. A small cell having a thin brass annular diaphragm is buried at the desired position with pipe and electrical connections to an air supply and electrical equipment. Air pressure within the cell equilibrates the external soil pressure as indicated by breaking the elec-

trical contact and the pressure is read on a pressure gage. Typical calibration results are given.

Tests of boilers with bagasse as fuel, E. W. KERR (*Louisiana Stas. Bul. 160 (1916), pp. 58, figs. 5*).—Continuing work previously noted (E. S. R., 22, p. 115), data are presented obtained from several series of boiler tests made at sugar factories during the grinding seasons of 1909, 1910, 1914, and 1915. The general purpose of these tests was to study the fuel economy of bagasse as affected by varying the size and form of the combustion chamber, the air supply, the amount of overload, and the size of grate.

In 1909 twenty tests were made in five sugar factories, seventeen of which were on bagasse-burning boiler plants and the remaining three on oil-burning plants. The first plant has one 300-horsepower Stirling boiler with 3,000 sq. ft. of heating surface for bagasse and four 125-horsepower horizontal return tubular boilers for oil. The second factory has eight horizontal return tubular boilers for bagasse, making a total of 9,097 sq. ft. of heating surface and giving 758 horsepower. The third factory has four horizontal return tubular boilers for bagasse, each having 1,260 sq. ft. of heating surface, making a total of 421 horsepower. The fourth factory has nine boilers for bagasse, having a total of 16,600 sq. ft. of heating surface and a capacity of 1,333 horsepower. The fifth factory has five internally fired boilers with a total of 1,500 horsepower. All the bagasse boilers have Dutch oven furnaces.

The tests on these plants showed that decreasing the load on heavily overloaded boilers resulted in increased economy. Little change in economy could be produced by attempts to reduce the air supply by closing the ash pit doors or the fuel hopper doors. However, regulation of the draft by means of the stack damper resulted in a substantial increase in economy. An increase in evaporation of 26 per cent resulted from halving the furnace draft in a plant having a very high chimney by partially closing the flue dampers. The best fuel economy was found in furnaces having the highest temperatures. The highest furnace temperatures were invariably in the furnaces having the highest rates of combustion and the highest carbon dioxide content in flue gases. The power development by the boilers with bagasse as fuel varied from 0.89 to 1.12 horsepower per ton of cane per 24 hours, the average being 1.02. The total power development in the plant burning oil and bagasse together was 1.8 horsepower per ton of cane per 24 hours.

In 1910 a series of tests was made in connection with experiments on the question of bagasse drying. The tests were all made on a Stirling boiler with 1,000 sq. ft. of heating surface. It was found in these tests that boiler efficiency is lowered by excessive draft. Forced draft gave higher efficiency than stacked draft. This is attributed to the fact that the blower causes reduced vacuum in the furnace and consequently less leakage of air. The stack heat loss was very high, the average being 45.16 per cent.

In 1914 and 1915 tests were made for the purpose of securing data regarding the effect of rate of combustion, volume of combustion chamber, form of combustion chamber, methods of feeding bagasse, and leakage of air into the setting upon boiler efficiency. Special attention was also given to the question of flue gas analysis. The tests were made upon four typical bagasse boilers and settings.

It was found that no particular advantage was indicated in tests of a boiler with a combustion space of unusual size and form. Higher efficiencies were obtained with a boiler having a much smaller combustion space. The highest efficiencies were obtained with higher rates of combustion. The highest rate of combustion obtained in any of the tests was 225 lbs. of bagasse per square foot of grate surface per hour in a setting with a large combustion

space. It was further found that with a large grate and open setting, together with a bagasse feeder that excluded air poorly, it was easy to have too much stack vacuum. On the other hand, it was found that a relatively small grate, in connection with a close setting and a hopper that excludes air, not only can be operated efficiently with high draft, but actually requires it.

With reference to flue gas analysis, it was found that the loss due to incomplete combustion of carbon was in most cases small as compared with the loss due to excess air. In practice it was found that if the damper is so set as to obtain a very high percentage of carbon dioxide by reducing the air there is danger of incomplete combustion due to lack of air in portions of the fuel bed.

The horsepower actually developed per ton of cane ground per 24 hours varied from a minimum of 1.16 where the fiber in the cane and the efficiency were low to a maximum of 1.44 where both the fiber and efficiency were high. In practically all cases the tests showed that boilers operated at overload gave efficiencies equal to or greater than when operated at rated or underload.

**Cereal dust explosions**, B. W. DEDRICK (*Oper. Miller*, 21 (1916), No. 12, pp. 452, 453; *Miller's Rev.*, 35 (1917), No. 12, p. 332).—Conclusions drawn from investigations conducted at the Pennsylvania State College, in cooperation with the Bureau of Chemistry of the U. S. Department of Agriculture and the Bureau of Mines of the U. S. Department of the Interior, are as follows:

“Hard substances, such as pieces of iron, nails, and stones, while producing sparks in passing between the grinding disks of attrition mills or other forms of disk mills along with material being ground produce no explosions, as the spark does not seem to possess sufficient intensity of heat or surface to cause ignition, and are almost instantly out as soon as emitted. . . .

“Matches are not more dangerous than the metal or stone substances in the case of disk mills or millstones, because they are fired almost instantly when coming in contact with the plates at the eye and smothered out before issuing from the mill. None of the matches were ignited when issuing from the mill. With rolls it is possible for the match to become ignited while passing between the rolls and cause a fire or possible explosion, the match stick lodging and burning, furnishing sufficient flame and heat surface.

“The spark or arc produced by static electricity does not seem to possess sufficient heat to ignite or cause an explosion of material or cereal dust as ordinarily produced in flour or cereal mills. . . . Only an electric arc, a naked flame, as a torch or lamp or burning match, apparently gives sufficient surface contact and heat to cause ignition of dust and cause an explosion which may produce merely a flash or an explosion more or less violent.

“An initial explosion may propagate and cause a flame to travel quite a long distance through conveyors and spouts. A conveyor does not seem to offer any obstruction to the flash or flame traveling through it or along its length. A damper in the spout below the mill is quite effective in preventing the flame from passing into the spout or conveyor below, so far as it relates to the ordinary light explosion, but it is possible for the flame in some instances to pass by the damper with a heavier explosion, though the force of the explosion or flash is checked or confined to the immediate vicinity of the damper. Another damper following the first would undoubtedly prevent any flame from reaching the spout or conveyor.

“When a secondary explosion follows it is generally more violent or possesses more force than the first explosion and is of wider extent.

“Dust in motion, as agitated by the blowing fan or caused by the jarring down or the sudden fall or cave in of flour or feed sticking around the side of

bins, is more liable to cause an explosion when a naked light comes in contact with it than the dust quietly floating in a room or bin."

Building code suggestions (*Nat. Lumber Manfrs. Assoc., Engin. Bur. Tech. Letter 4 (1916), pp. 12, figs. 10*).—Fire stops, careful workmanship, and proper selection of materials are discussed as safeguards in frame dwelling construction.

Building code suggestions (*Nat. Lumber Manfrs. Assoc., Engin. Bur. Tech. Letter 5 (1916), pp. 11, figs. 9*).—Chimneys, smoke pipes, and fireplaces are discussed in their relation to the fire hazard in dwellings, and detailed provisions for incorporation of these features in building codes are given.

Tests of fire retardents, with special reference to the shingle roof, H. and A. VON SCHRENK (*Nat. Lumber Manfrs. Assoc., Engin. Bur. Tech. Letter 2 (1916), pp. 4, figs. 2*).—Preliminary tests of fire retardents for use on shingle roofs are reported.

The tentative conclusion is drawn that "several compounds are now available which, if properly applied to wooden shingles, will give a shingle roof a very high degree of fire resistance. These same compounds at the present time have every guaranty of permanence, so far as this can be determined from a chemical investigation. They are insoluble in water and give a roof a pleasing appearance. For interior work, or for such places where direct weathering is of secondary importance, a very considerable number of compounds can be recommended, ranging from good mineral paints to more expensive materials."

The construction of cow houses (*Bd. Agr. and Fisheries [London], Leaflet 241 (rev.); Jour. Bd. Agr. [London], 23 (1916), No. 5, pp. 447-459, figs. 4*).—This article deals with the principal factors to be considered in the construction of cow houses in England, as follows: Site, general construction of buildings, internal design, air and floor space, ventilation, and lighting.

The construction of dipping tanks for cattle (*Rhodesia Agr. Jour., 13 (1916), No. 4, pp. 523-534, pls. 2*).—Specifications and working drawings of a serviceable and economical dipping tank are presented and discussed.

Ice houses and ice supply, F. M. WHITE and C. I. GRIFFITH (*Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul., 6 (1916), pp. 23, figs. 5*).—This bulletin gives general information on ice harvesting and ice houses and discusses factors in the construction of ice houses, including size, insulation, foundation and floors, walls, doors, and ventilation. Designs for a farm ice house, a combination ice and cold storage room, and a homemade ice box are included.

Design of bins for materials, E. McCULLOUGH (*Cement Era, 15 (1917), No. 1, pp. 42-44, fig. 1*).—This article deals with the design of circular reinforced concrete bins for grain, coal, and other materials. Curves of data are included.

Farm sanitation, C. L. McARTHUR (*Arkansas Sta. Bul. 127 (1916), pp. 3-24, figs. 9*).—This bulletin deals with the location of farm buildings, the farm water supply, farm privies and sewage disposal, disinfection, flies and mosquitoes, and disposal of waste material and dead carcasses.

Sewage purification, H. VERRIÈRE (*Ann. Ponts et Chaussées, 9. ser., 32 (1916), pt. 1, No. 2, pp. 159-224, figs. 2*).—This article deals at some length with causes of the pollution of surface waters, the dangers of such pollution, self purification of surface waters, and circumstances making artificial purification of sewage necessary.

Some theoretical considerations bearing on the performance of biological sewage purification plants, G. T. P. TATHAM (*Jour. Soc. Chem. Indus., 35 (1916), No. 13, pp. 711-715; abs. in Chem. Abs., 10 (1916), No. 21, p. 2779*).—A theoretical discussion of the mean time of contact of sewage liquid with filter-

ing material and the relation between the degree of purification and mean time of contact is given, together with the results of tests on fine and coarse, shallow and deep filters.

Theoretical laws and tabular data are derived which are suggested for use in the design of sewage purification systems. The laws indicate "that the purification should not even theoretically be directly proportional to the mean time of contact. The relations given involve only one constant  $a$  [oxygen avidity constant] which is dependent jointly on the nature of the sewage liquor and the method of purification adopted. . . . It is the numerical measure of the rate at which the sewage pollute is oxidized when it is present in unit concentration."

The equations and tables "give mathematical expression to the fact . . . that the size of the plant required to give a specified degree of purification increases very greatly per unit increase in the percentage purification as the latter itself increases. . . . Given the flow, it has been shown that the mean time of contact is proportional to the liquid content of the purification plant, and this in turn depends on the biological conditions obtaining inside the filter and on the physical nature of the filtering medium."

### RURAL ECONOMICS.

**Proceedings of the ninth Rural Life Conference** (*Alumni Bul. Univ. Va., 3. ser., 9 (1916), No. 4, pp. 417-496*).—This volume contains abstracts of the papers read at the ninth annual conference held at the University of Virginia summer school, in 1916, and relating principally to rural school and church problems.

**A rural survey of Lane County, Oregon**, F. C. AYER and H. N. MORSE (*Univ. Oreg. Bul., n. ser., 13 (1916), No. 14, pp. 109, figs. 32*).—This survey relates primarily to the rural and educational conditions found in Lane County.

[**Rural reforms in the organization of Spanish agriculture**], G. FERNÁNDEZ DE LA ROSA (*Bol. Agr. Téc. y Econ., 8 (1916), Nos. 85, pp. 41-50; 86, pp. 157-166; 87, pp. 221-230; 88, pp. 318-324; 89, pp. 396-405; 91, pp. 583-593*).—The author discusses some of the causes for the lack of progress in Spanish agriculture, and advocates the federation into a national organization of all agencies working for agricultural improvement.

**Semi-centennial history of the Patrons of Husbandry**, T. C. ATKESON (*New York: Orange Judd Co., 1916, pp. XII+364, pls. 24*).—In this volume are recounted the activities of the Patrons of Husbandry from the initiation of the order in 1865 to date, together with statements regarding its principal officers.

**History of the state agricultural and mechanical society of South Carolina**, W. A. CLARK, W. G. HINSON, and D. P. DUNCAN (*Columbia, S. C.: The R. L. Bryan Co., 1916, pp. XXII+306, pls. 13*).—This volume gives the history of the society from its foundation in 1839, and describes its activities and the men connected with it as officers.

[**Agricultural law of New York**] (*N. Y. Dept. Agr. Bul. 83 (1916), pp. 1955-2145*).—There have been brought together in this bulletin the laws of the State which affect agriculture.

**The federal farm loan system**, H. MYRICK (*New York: Orange Judd Co., 1916, pp. 239*).—The author explains the various provisions of the Federal Farm Loan Act and gives the full text of the act together with amortization tables.

**The farm mortgage handbook**, K. N. ROBINS (*Garden City, N. Y.: Doubleday, Page & Co., 1916, pp. XIII+241*).—The author describes the methods used by institutions dealing in farm mortgages in granting the mortgage and in its sale to the public. He points out some differences between the placing on sale of farm mortgages and those of other types.

The land credit problem, G. E. PUTNAM (*Bul. Univ. Kans.*, 17 (1916), No. 18, pp. 107).—The author discusses land mortgage credit in the United States, the rural credit movement, and credit for landowners, tenancy and land tenure reform, and the Federal Farm Loan Act.

The agricultural bank of the Philippine Government, J. L. MANNING (*Ann. Rpt. Treas. Philippine Islands*, 1914, pp. 52-58).—In these pages are described the activities of the bank, with a statement of its resources and liabilities showing the progress made during the six years of its existence.

Cooperation in the New World, L. SMITH-GORDON (*Better Business*, 1 (1916), Nos. 3, pp. 212-222; 4, pp. 296-314; 2 (1916), No. 1, pp. 54-73).—The author describes the various types of cooperative agricultural organizations found in his travels through the eastern and central parts of the United States.

Report on the working of cooperative societies in Bihar and Orissa for the year 1915-16 (*Rpt. Work. Coop. Soes. Bihar and Orissa*, 1915-16, pp. 4+36+8+2, pl. 1).—This report continues the information previously noted (*E. S. R.*, 36, p. 290).

A manual on the preparation of crop forecasts in India (*Dept. Statis. India, Manual Crop Forecasts India*, 1916, pp. 4+11+46).—In this publication are discussed the history and development of crop forecasts, copies of the instruction sheet regarding the preparation of the forecasts for various crops, and the methods in use in certain provinces.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt.*, 2 (1916), No. 12, pp. 121-140, figs. 12).—In this number are given the acreage, average yield, total production, value and monthly prices of the principal farm crops by States, a revised estimate of the acreage contracted for by canneries, the condition of winter truck crops, the condition of winter wheat and rye sown in the autumn of 1916, the estimated farm value of important products and the range of prices of agricultural products at important markets, the production of cabbage, tobacco, sugar beets, and beet sugar during 1916, a series of tables showing the production of the principal agricultural products by States and the monthly prices, and other data.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt.*, 3 (1917), No. 1, pp. 12, figs. 8).—This number contains the usual data regarding the estimated farm value of important products and the range of prices of agricultural products at important markets, together with data showing the number and value of live stock on farms January 1, the exports of horses and mules, monthly prices of milch cows, calves, beef cattle, sheep, lambs, hogs, wool, and bulls, also index numbers of prices of meat animals. Statistical data are also shown giving the prices of live stock by ages and classes. Data are given showing the condition of truck crops, stock of potatoes on hand January 1, the yearly marketings of live stock, etc.

Missouri crop review for 1916, W. L. NELSON (*Missouri Bd. Agr. Mo. Bul.*, 14 (1916), No. 12, pp. 26, figs. 5).—In this report are given the acreage, average and total yield, average farm price of principal farm products December 1, 1916, and the number of live stock being fed compared with previous years.

Farm lands in New Jersey, F. DYE and J. G. LIPMAN (*Trenton, N. J.: State Bd. Agr.*, 1916, 3. rev. ed., pp. 51, pls. 11).—In this revision (*E. S. R.*, 31, p. 390) the authors discuss by counties the natural characteristics and adaptability to various farm crops of the farm lands, and also include special chapters on the climate and the fruit and vegetable, canning, poultry, and shellfish industries.

[Agriculture in Argentina], H. MIATELLO (*Bol. Min. Agr. [Argentina]*, 20 (1916), No. 7-8, pp. 537-567, figs. 36).—The author outlines the development of animal and crop production and discusses agricultural colonization and im-

migration, transportation of agricultural products, and manufacturing industries allied to agriculture.

[Agricultural statistics of Argentina] (*Extract. Estadis. Argentina, 1915, pp. 342-353*).—In these pages the area, production and value of the principal crops for 1915 are given, with comparative data for earlier years.

[Agricultural statistics of São Paulo], P. DE MORAES BARROS (*Relat. Sec. Agr., Com. e Obras Pub. São Paulo, 1914, pp. 101-133, pls. 3*).—In these pages are given data as to the production, imports, and exports of important agricultural products.

Agricultural statistics of Uruguay (*Estadis. Agr. [Uruguay], 1915, pp. XIV+134*).—In this report are shown the movement of agricultural products, the area and production of the principal crops, the number of live stock and the number slaughtered in 1915, and comparative data for earlier years.

Acreage and live stock returns of England and Wales (*Bd. Agr. and Fisheries [London], Agr. Statis., 51 (1916), No. 1, pp. 36*).—This report continues data previously noted (E. S. R., 35, p. 590).

Agricultural statistics of Portugal (*Estatis. Agr. Portugal, No. 4 (1914), pp. 272*).—In this volume are given statistical data for minor subdivisions relating to rural population, soil, climate, area and production of crops, number of live stock, and consumption of animal products.

[Agriculture in Sweden], edited by J. GUINCHARD (*In Sweden. Stockholm: Govt., 1914, 2. ed., vols. 1, pp. 1-81, 117-124; 2, pp. 27-165, figs. 85*).—In these volumes are discussed the topography, climate, flora, fauna, rural population, rural husbandry, agricultural credit, and agricultural legislation.

Agriculture [in Japan], S. SATO (*Japan Year Book, 1916, pp. 331-350*).—These pages continue the information previously noted (E. S. R., 34, p. 92).

[Agriculture in Chosen] (*Ann. Rpt. Reforms and Prog. Chosen (Korea), 1914-15, pp. 118-129, pls. 4*).—These pages continue the information previously noted (E. S. R., 34, p. 792).

[Agriculture of New Zealand] (*New Zeal. Off. Yearbook 1915, pp. 493-594, pls. 2, figs. 2*).—These pages continue the data previously noted (E. S. R., 33, p. 395) adding data for 1915.

## AGRICULTURAL EDUCATION.

Report on the Agricultural Instruction Act, 1914-15 (*Canada Dept. Agr. Sess. Paper 15c (1916), pp. IV+5-214*).—This report comprises a summary showing the chief purposes for which the funds hitherto available under this act have been expended in the various provinces of the Dominion, and a review by provinces of the work carried on during the past fiscal year, including financial statements showing receipts and expenditures under the Agricultural Education Act of 1912, and the Agricultural Instruction Act to March 31, 1915. Appendixes relate to the rural school and school consolidation in Canada and the United States; school instruction in agriculture, farm mechanics, and home economics in Canada and the United States; farm demonstration work in the United States; women's work in Canada, etc.

[Agricultural and forestry education institutions in Sweden], edited by J. GUINCHARD (*In Sweden. Stockholm: Govt., 1914, 2. ed., vol. 2, pp. 119, 125-135, 187-189, figs. 2*).—An account is given of the historical development and present organization of agricultural education institutions, including agricultural, forestry, and veterinary high schools, agricultural schools, forestry schools, dairy schools, people's high schools, farmers' schools, schools of agricultural economy for women, and farriery schools.

The Wisconsin county training schools for teachers in rural schools, W. E. LARSON (*U. S. Bur. Ed. Bul. 17 (1916), pp. 40, pls. 4, figs. 2*).—This bulletin

contains a brief history of these schools, the text of the county training school law, and a report, including statistical data, on the provisions for buildings, courses of study, experience and preparation of teachers, preparation of students, the work done by graduates of these schools, the work of these schools outside of training of teachers, advantages of the training school as an institution for training country teachers, suggestions for improving the work of these schools, and other institutions in Wisconsin preparing teachers for country school work.

There are now 30 county training schools in Wisconsin, in which country school conditions are kept constantly in mind. Every school gives at least 20 weeks to the study of agriculture and some give as much as a year; nature study is emphasized throughout the course, practically all of the schools have introduced in some form the study of rural sociology and rural economics, and many give domestic science and manual training; seven have actual practice departments in connection with their institutions, while the remainder secure practice work in the public schools of the village or city in which they are located.

The training of teachers for agricultural instruction (*Agr. Gaz. Canada*, 3 (1916), No. 10, pp. 916-924).—This is an account of the present status of the training of teachers for agricultural instruction in the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

Summer school for teachers (*Agr. Gaz. Canada*, 3 (1916), No. 10, pp. 925-932, figs. 2).—A report is given on the summer schools for teachers of agriculture held in 1916 in the Provinces of Prince Edward Island, New Brunswick, Ontario, and Saskatchewan.

Information relating to the establishment and administration of county agricultural schools and agricultural departments (*Bul. Bd. Ed. Mass.*, No. 23 (1916), pp. 80).—This bulletin contains comparative statements, aided in several instances by parallel columns, with reference to the authorization, control, organization, location, equipment, courses of study, qualifications of teachers, methods of instruction, conditions of admission, employment of pupils, expenditures of money, and digest of the procedure required for state approval and reimbursement, of county agricultural schools and agricultural departments in high schools, to indicate the requirements and advantages of both. The text of an act to provide for the establishment and maintenance of an independent agricultural school, an example of a farm bureau memorandum of agreement, a memorandum regarding the classification of expenditures of state-aided vocational agricultural schools, and an example of per capita cost returns, are appended.

Agricultural education in secondary schools, L. S. HAWKINS (*Univ. State N. Y. Bul.* 624 (1916), pp. 87, pls. 29, fig. 1).—This is an account of agricultural education in secondary schools in New York. It deals with (1) laboratory and field instruction, including poultry class projects at the Hamburg and Highland high schools, a farm crops class project at the Le Roy High School, a dairy class project at the Perry High School, a joint project by the agricultural and home making departments at Lowville, and stock judging at Canton and Alfred; (2) home projects, (3) summer work of the teachers of agriculture, (4) the summer conference of teachers of vocational agriculture at the New York State College of Agriculture, including an outline of a four-year course in agriculture being tried out; (5) apprentice teacher training by the New York State College of Agriculture (E. S. R., 33, p. 795); (6) courses in home making; (7) extension work; and (8) the growth and development of agricultural instruction in a small high school.

Women's institutes of Ontario, 1915 (*Rpt. Women's Insts. Ontario, 1915, pt. 1, pp. 191*).—This report contains the proceedings of the annual conventions of 1915, selected papers, and statistical data. The work now comprises 892 branches with a membership of about 30,000.

Some suggestions on the organization of school gardens, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucuman, 6 (1915), No. 4, pp. 139-148*).—In this discussion the author distributes school garden instruction over three years and suggests the work to be undertaken in each.

A course in agriculture for the high schools of Michigan, W. H. FRENCH (*Mich. Agr. Col., Dept. Agr. Ed. Bul. 14 (1915), pp. 76, figs. 3*).—This bulletin contains an outline of a course in agriculture for the high schools of Michigan. It includes suggestions and syllabi on the several subjects to be taught; suggestions to school officers on the qualifications and time of employment of teachers of agriculture, rooms and equipment, etc., and suggestions to teachers on methods of instruction, including extension work, school and home projects, field trips, etc. The course in agriculture is elective and includes one unit in each grade of the high school, thus making a four-year course. Each agricultural subject constitutes a half unit. There should be daily recitations for two or three days each week, other days being given to laboratory work and to study and observation in the experiment plat and on farms. An agricultural reference library and sample score cards are appended.

Elementary agriculture, J. S. GRIM (*Boston: Allyn and Bacon, 1916, pp. XVI+490+12, pl. 1, figs. 336*).—This book consists of five parts, viz, rural life and activities, the soil and its improvement, crops, stock, and farm economics, with practical questions, suggested home exercises, suggestions to teachers, and references to the literature at the end of each chapter. Charts showing the distribution of United States products, lists of farm journals and magazine articles, a sample constitution and by-laws of a boys' pig club, directions for the use of Farmers' Bulletins, a report of a pupil's project, etc., are appended.

Chemistry of the farm and home, W. E. TOTTINGHAM and J. W. INCE (*St. Paul, Minn.: Webb Publishing Co., 1916, pp. 434, figs. 115*).—This text, for secondary schools giving instruction in agriculture, comprises five chapters in general chemistry to serve as a foundation for the succeeding chapters on chemistry as applied to the plant and its products, the soil, fertilizers, farm manure, the animal and its products, feeding of animals, dairy products, human food and dietetics, and miscellaneous materials of importance in daily life. Each chapter ends with a summary and review questions. The book concludes with 126 laboratory exercises, and appendixes containing a list of supplementary books and bulletins, data on soils and feeding stuffs, required chemicals and apparatus, etc.

A laboratory manual of soil bacteriology, E. B. FRED (*Philadelphia and London: W. B. Saunders Co., 1916, pp. 170, figs. 13*).—This laboratory manual is intended primarily for students of soil bacteriology, soil chemistry and physics, and plant pathology, it being assumed that the student has had previous training in general bacteriology and chemistry. The manual consists of exercises in soil bacteriology which, as far as possible, are planned to give quantitative results, formulæ and methods, a list of apparatus for one student, a list of some of the more important books and journals treating of bacteriology, and laboratory rules.

Sixty-two experiments in crops, C. L. QUEAR (*Muncie, Ind.: Industrial School Service, 1916, pp. 89, figs. 45*).—This laboratory manual has been prepared for the seventh, eighth, and ninth grades of the public schools. The experiments are arranged in four sections, viz, plant composition, cereal crops, forage crops, and plant economics, following somewhat carefully in the order

of topics presented the following psychological principles: (1) The instincts which characterize the pupil during his adolescent period, (2) the ideas and experiences which he has formerly acquired which relate themselves in such a way as to help him in the clear grasp of agricultural facts, (3) the economic phase, and (4) habits previously acquired by the pupil.

**The chemistry of the garden**, H. H. COUSINS (*London: Macmillan & Co., Ltd., 1916, rev. ed., pp. XIX+143*).—This small volume treats the subject in a nontechnical way under the following chapters: How plants grow, the air, the soil, the fertility of the soil, manuring, organic manures, artificial manures, garden manuring, fungicides, and insecticides.

**Practical school and home gardens**, G. W. HOOD (*Lincoln, Nebr.: Long and Co., 1916, pp. [6]+181, figs. 114*).—This book is suitable for school work between the sixth and twelfth grades and for home gardening. Chapters are devoted to the value of a plant, planning the garden, the seed and how to plant it, the soil and its treatment, the hotbed and the cold frame, plants that should be started in the hotbed or the cold frame, spray material and spray machinery, vegetables grown for their roots, vegetables grown for their green parts, vegetables grown for their fruit and seed, and perennial vegetables. At the end of each chapter are review questions and references to literature. Directions are added for making 24 gardens, including suggested plans and records.

**Agricultural woodworking**, L. M. ROEHL (*Milwaukee, Wis.: The Bruce Publishing Co., 1916, pp. 137, figs. 122*).—This is a group of problems for rural and graded schools, agricultural high schools, and the farm workshop. They include plans and lists of material required for making practical articles used in the home and about the farm, hog, poultry, and pigeon houses, a silo form, implement shed, corncrib, combined dairy and horse barn, combined horse and cow barn, plan for a farmstead, etc. A number of these problems appeared in a pamphlet entitled *Manual Training for the Rural Schools* (E. S. R., 36, p. 96).

### MISCELLANEOUS.

**Twenty-ninth Annual Report of Alabama College Station, 1916** (*Alabama Col. Sta. Rpt. 1916, pp. 28*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, and reports of the director and heads of departments on the work of the station during the year.

**Twenty-eighth Annual Report of Colorado Station, 1915** (*Colorado Sta. Rpt. 1915, pp. 30*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1915, a report of the director on the work and publications of the station, and departmental reports.

**Twenty-ninth Annual Report of South Carolina Station, 1916** (*South Carolina Sta. Rpt. 1916, pp. 64*).—This contains the organization list, a report of the director on the work of the station, a financial statement for the fiscal year ended June 30, 1916, departmental reports, of which that of the botanist and plant pathologists is abstracted on page —, and two special articles abstracted elsewhere in this issue.

**Monthly bulletin of the Western Washington Substation** (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1917), No. 11, pp. 16, figs. 2*).—This number contains brief articles on the following subjects: Udder Diseases and Their Treatment, by J. W. Kalkus; Celery Culture in Western Washington, by J. L. Stahl; and Breeding for Egg Production, by Mr. and Mrs. G. R. Shoup.

## NOTES.

---

**Arkansas University.**—The state legislature has appropriated \$481,000 for the ensuing biennium for the divisions of liberal arts, agriculture, engineering, and education. This is an increase of approximately 50 per cent over any previous appropriation. An act was also passed whereby the university will hereafter be maintained by a special tax of four-ninths of one mill on all taxable property in the State.

**Delaware College and Station.**—The state legislature has appropriated a total of \$285,890.27 to the college for the ensuing biennium. Among the items authorized are \$125,000 for the new dormitory at the women's college, \$32,000 per annum for the maintenance of that college, \$32,000 for a new heating plant, \$14,000 per annum for general maintenance, \$10,000 per annum for the maintenance of the agricultural department, \$7,890.27 for agricultural extension, and \$4,000 to replace the loss of revenue due to the transfer of the fertilizer control work to the State Board of Agriculture.

**Hawaii College.**—Dr. J. F. Illingworth has resigned as entomologist to accept an entomological position in north Queensland for a three-year period, beginning about June 1.

**Illinois University.**—A field of 32½ acres, located near Elizabethtown in Hardin County, has been presented to the university for experimental purposes by a donor whose name is withheld. This is the twenty-sixth tract to be given the university for agricultural work. In addition two pieces of land have been purchased and 16 are under lease, making 44 fields under cultivation by the college of agriculture in different parts of the State.

**Indiana Station.**—Director Arthur Goss, who has been at the head of the station since 1903, has resigned, effective September 1, to give his entire attention to his extensive farming interests near Vincennes.

**Iowa Station.**—A. A. Dowell, instructor in animal husbandry, has resigned to assume charge of the department of animal husbandry in the University of Alberta, vice Kenneth McGregor, who is to engage in farming.

**Kansas College and Station.**—A law was recently passed abolishing the state boards of control, educational administration, and corrections, and creating a single board in their stead. The new board consists of five members of whom the governor is chairman, and will have charge of all state educational, benevolent, and penal institutions beginning July 1. Provision is also made in the act for the appointment for all institutions under its jurisdiction of a general manager at a salary not to exceed \$6,000 per annum.

The legislature has appropriated \$80,000 to the college for the purchase of land to be used for animal husbandry, dairy, and poultry farms, and \$50,000 for an addition to the agricultural building.

Warren Knaus, of the class of 1882, has given to the entomological museum of the college his extensive collection of Coleoptera.

M. N. Levine, research assistant in plant pathology at the Minnesota Station, has been appointed assistant plant pathologist.

**Louisiana Stations.**—W. R. Griffing has been appointed assistant plant pathologist.

**Michigan College and Station.**—V. M. Shoemith, professor of farm crops and farm crop experimentalist at the station since 1910, has accepted a position as superintendent in the development of a 4,300-acre tract of land near Grand Rapids.

**Massachusetts College and Station.**—Dr. A. E. Cance, head of the department of agricultural economics, has been granted leave of absence to work in co-operation with the New England Committee of Food Supply, which is endeavoring to organize a more efficient system of distributing food products. Miss Lorain P. Jefferson, research secretary of the division of rural social science, has been appointed acting head of the department during his absence.

F. A. Waugh has been granted six months' leave of absence beginning April 1 to take up work as consulting landscape architect in the Forest Service of the U. S. Department of Agriculture. In this capacity he will visit many of the National Forests with a view to suggesting means to conserve their natural beauties and outline a general policy for the landscape treatment of forest areas.

Robert S. Scull has been appointed assistant chemist beginning February 1.

**Minnesota University and Station.**—The division of agricultural biochemistry has completed its organization and equipment for instruction and research in plant chemistry. Opportunity is now afforded for graduate work in this subject leading to the M. S. and Ph. D. degrees. The research projects available for investigation in 1917-18 include the strength of wheat flour, the chemistry of resistance to disease in plants, the enzymes of fruits and their relation to ripening processes, the chemistry of pollen, and protein investigations.

The resignations are noted of J. Russell Winslow, assistant in the division of agricultural biochemistry, effective January 31; E. C. Higbie, superintendent of the West Central School and substation at Morris, effective July 31; and F. J. Piemeisel, research assistant in plant pathology, to become scientific assistant in the Office of Cereal Investigations of the U. S. Department of Agriculture.

**Missouri University.**—Recent appointments include Roy Hastings and Paul B. Naylor as assistants in agricultural extension, and T. S. Townsley, formerly assistant in poultry husbandry at the Kansas College, as extension instructor in poultry husbandry.

**Nebraska Station.**—R. R. Spafford has been appointed assistant in farm management.

**Nevada University and Station.**—The term of office of regents of the university has been extended to ten years instead of from two to four years, one regent henceforth being elected every two years for the full term. The legislature made an appropriation of \$2,000 for general running expenses of the station.

**Rutgers College.**—Under a recent act of the state legislature the scientific departments of the college have been designated as the State University of New Jersey.

**New Mexico College and Station.**—Dr. George E. Ladd has resigned as president and has been succeeded by Dr. A. D. Crile.

The station has received an increase of \$2,500 per year in its State appropriation from the recent legislature. J. G. Hamilton, assistant agronomist has resigned, effective March 1, to become county agent in Valencia County.

**Cornell University.**—A series of news notes for the use of the press dealing with the use of our agricultural resources, such as the need of supplying the staple foods, the increase of food production and elimination of wastes in marketing, the development of home gardens, and the lessening of food wastes

and other wastes on the farm and in the home has been begun. These new notes supplement the regular series of press bulletins, which will be continued as heretofore.

**North Carolina College and Station.**—The station officials are cooperating with the extension division to promote a campaign for safe farming. The State seems to be well aroused as to the advantages of producing food and feed crops on the home farm, several thousand letters having been received requesting information as to the proper cultivation, fertilization, etc., of these crops. The question of the home garden has aroused especial interest among both city and country people.

E. E. Culbreth, assistant in the division of markets and in charge of the accounting systems of the credit unions, has resigned to accept a commercial position. Dr. I. M. Hawley has been appointed nursery inspector.

**Ohio Station.**—W. C. Boardman and O. H. Smith, assistants in the soil survey, have resigned. Sidney Bliss has been appointed assistant in the department of soils.

**Oregon College and Station.**—O. G. Simpson, assistant professor of dairy manufactures and dairy manufacturing specialist, has resigned to become manager of the Oregon Cooperative Dairy Exchange. J. O. Beck has been appointed instructor in dairying, vice D. C. Howard, who has been appointed county agent of Columbia County.

**Pennsylvania College.**—A tract of 60 acres adjoining the present experimental orchard is to be developed with a view to affording instruction to students in the commercial operations of fruit growing. About 20 acres will be planted to apples, 7 to peaches, 4 to grapes, 8 to small fruits, 1 each to pears, plums, and cherries, and 3.5 to nuts, while 5 acres will be used for variety tests and studies of the botanical species from which the fruits have sprung. It is planned to provide eventually a foreman's house and facilities for spraying, packing, etc. The courses are to be so arranged as to permit of spending half-day periods at the orchard.

J. B. Scherrer, of the New Hampshire College and Station, has been appointed assistant professor of vegetable gardening extension, effective April 15, and J. Martin Fry, assistant in agricultural extension, beginning February 1. Ralph A. Waldron, instructor in botany, has resigned to take up graduate work at the University of Pennsylvania.

**Porto Rico Federal Station.**—Harvey E. Thomas, assistant plant pathologist at the Virginia Station, has been appointed plant pathologist.

**South Carolina College and Station.**—H. W. Barre has been appointed director of research, beginning April 4. He will thus become director of the station, vice J. N. Harper, whose resignation has been previously noted, but not dean of the college, that office having been dropped for the present.

**Utah College and Station.**—A. W. Ivins of Salt Lake City, J. W. Knight of Provo, Mrs. Lois C. Hayball of Logan, A. G. Barber of Logan, and Frank B. Stephens of Salt Lake City have been appointed to the board of directors, vice Thomas Smart, J. Q. Adams, J. M. Peterson, Annie K. Hardy, and Joseph Quinney, jr.

The policy of the State toward the college and station was slightly changed by the last legislature by substituting for the continuous appropriation method the inclusion of estimates in the governor's budget. A substantially increased appropriation for the ensuing biennium was granted, of which the station receives \$7,500 additional and the extension work \$5,000 additional, together with \$61,100 for buildings and improvements and \$6,000 for pure bred live stock and pasture.

**Washington Station.**—A state office of farm markets has been established, attached to the station. The director is to be appointed by the director of the station with the approval of the governor. The study and improvement of market conditions is to be taken up and a market news service will be maintained. The act carries an appropriation of \$15,000 for the biennium.

Dr. I. D. Cardiff has resigned as director of the station, his resignation to take effect during April.

**West Virginia University and Station.**—Under the will of the late Lawrence A. Reymann the station receives an estate of about 931 acres of improved land and a herd of about 125 pure bred Ayrshire cattle, the total value being about \$120,000. The land is located on Capon River, in Hardy County near the Virginia line, and is well equipped with buildings, farm machinery, etc., including a recently constructed cheese factory. The purpose of the gift is expressed as to promote, develop, and advance the science of agriculture in its most comprehensive scope, and in addition to give special attention to the breeding and development of Ayrshire cattle. The station obtained possession March 1, L. F. Sutton being placed in charge as superintendent.

**Wyoming Station.**—Earl O'Roke, instructor in zoology at the University of Kansas, has been appointed assistant zoologist and parasitologist beginning March 1.

**Canadian Experimental Farms.**—An experimental flax mill has been erected at the Central Experiment Farm at Ottawa and is being equipped for comprehensive experimental work in fiber manufacture. Field work with flax and hemp is also to be conducted at Ottawa, several branch stations, and elsewhere, in an attempt to determine the areas in Canada suitable for the industry and to work out problems connected with its development.

Research laboratories for special studies of grain rust are being established at Brandon, Manitoba, and Indian Head, Saskatchewan. W. P. Fraser, assistant biologist in Macdonald College, has been appointed to take charge of this work.

**Agricultural Development in Ontario.**—In a special effort to populate and bring under cultivation large areas in northern Ontario, an agricultural high school and demonstration farms at New Liskeard, a government creamery at the same place, a 50-acre demonstration field near Matheson, and a plant breeding station at Ft. William are to be established. W. R. Leslie, a graduate of the Manitoba College, is to take charge of the breeding station.

Plans are also under way for the necessary buildings and equipment for a new agricultural school to be established, through the Ontario Department of Agriculture, near Kemptville in eastern Ontario. It is intended to give useful and practical instruction in agriculture to young men between the ages of 16 and 25 who have left school and domestic science instruction to young women. It is not proposed to duplicate anything already being done in the Province unless to some extent the first two years of the course at the Ontario Agricultural College. The regular course will not be longer than two years and there may also be a number of short courses.

Special provision has been made in Ontario for the obtaining of homesteads by returning soldiers. These soldiers will first be sent to an agricultural training depot being established at the government experimental farm at Monteith, where they will receive instruction. When a sufficient number have been trained, a farm colony will be opened at some point along the railway in charge of a competent superintendent. Farms containing not over 80 acres will be laid out and so planned as to bring the various farm houses as closely together as possible. A 10-acre tract will be cleared on each farm, and when this is completed the farm may be allotted free of charge to a soldier. He may also receive machinery, live stock, etc., to the value of \$500, this being

reimbursable within twenty years. The final title to the land will be given after five years. The community system will be followed in supplying horses, other stock, and implements, and cooperative methods of buying and selling will be used.

Other plans for placing soldiers on the land are also under consideration.

**Agricultural Instruction in Western Canada.**—In 1916 the provincial ministry of agriculture of British Columbia, which until then had always been united with some other ministry, was made a separate and distinct department and placed in charge of William Manson.

During the past year 90 acres of the agricultural college site at the University of British Columbia have been cleared and prepared for cropping and for a botanical garden. A collection of upwards of 26,000 specimens, representing nearly 800 species, of the native flora of British Columbia, which has been made during the past four years by John Davidson, the Province botanist, is to be transferred to the university campus, as a nucleus for a botanic garden. The last session of the legislature appropriated sufficient funds to permit of a beginning to be made in the erection of suitable farm buildings and the purchase of live stock and equipment.

Regular degree courses in agriculture will not be offered in the college during the present academic year, but it is hoped that a series of short courses will be given, including the course on the scientific basis of agriculture offered as an elective last year (E. S. R., 34, p. 696). F. M. Clement, who for several years has been director of the Horticultural Experiment Station at Vineland, Ontario, has been appointed professor of horticulture and P. A. Boving, who for the past three years has been in charge of root investigations at MacDonald College, assistant professor of agronomy.

Agricultural instruction has recently been introduced into the high schools of British Columbia in a systematic way. The first class in the Province was organized in September, 1915, and was followed by similar instruction in four other high schools in September, 1916. The instruction is being given by agricultural specialists, and is attended by a total of about 130 boys and girls. A two-year course has been outlined for these schools including the study of soils, fertilizers, and drainage; fodder, grain, and root crops; vegetable and flower gardening; fruit growing; animal and poultry husbandry; dairying and bee keeping; farm accounting and marketing; farm mechanics for boys; and special practice in the purchase and preparation of foods for girls.

Equipment costing about \$400 is available in each school, with from one-half to one acre of land for experimental and demonstration plats. The salary of the instructor is paid by the provincial department of education, and the remaining expenses by the local authorities.

The Alberta Department of Agriculture began extension work in agriculture last spring with district agents in the field at various points in the Province. The minister of education is cooperating to the extent of making the time of the classes in school available to the agents for the carrying on of the work in cooperation with the teacher and inspector. The plan is to have the pupils take actual part in the growing of garden crops, the raising of chickens, and the feeding and management of young stock on their own farms. Initial group instruction in the laying out, planning, and general cultivation of the home garden is given in the schools, where leaflets and bulletins, seeds, and a limited number of eggs are distributed. Competitions in caring for stock are carried on and the season's program culminates in a fall fair held in conjunction with the district fair or at the most convenient school or village center. The work is being conducted in five centers and about 100 schools are taking part in it.

**Agricultural Progress in Latin America.**—A law recently enacted in Colombia provides for the establishment of a series of stations in which agricultural investigations, such as experiments and demonstrations, application of chemical fertilizers, and the cultivation and acclimatization of plants, will be carried on and exhibits will be made of modern agricultural machinery and tools. Each station will maintain a special agricultural meteorological bureau and be equipped for the study of insects injurious to plants, for analyses of soils and waters, and for the importation and distribution of seeds, plants, fertilizers, and animals for breeding purposes. It is also expected to issue a monthly bulletin as the official organ of these stations.

A proposition is under consideration in Argentina for the establishment of a central institution for experimental work in agriculture under the immediate direction of the minister of agriculture. This institution would be located in the capital and would contain at the start an agricultural chemical laboratory, an office for seed control, an office for the study and inspection of agricultural machinery, an office of agricultural botany, an office of vegetable pathology and agricultural entomology, and a meteorological observatory.

According to the *Bulletin of the Pan American Union* a practical school of agriculture has been opened at Aconcagua, in Chile, and steps have been taken to found an agricultural school for women in the Province of Aconcagua.

In Costa Rica a professional school for girls was inaugurated on June 1, 1916, in San José, equipped for giving practical instruction in domestic arts and science and such other subjects as may be deemed desirable.

The agricultural school at Challapata, Bolivia, for the instruction of the natives has been moved to Rosario Plantation, near the town of Challapata, and enlarged.

It is announced that the Department of Fomento, in Mexico, has decided to establish a nursery for tropical plants in one of the States of the Republic bordering on the Gulf of Mexico. The principal feature of this nursery will be to furnish to small farmers the most desirable varieties of tropical food plants suitable for cultivation on the east coast of Mexico, such as bananas, mangos, pineapples, alligator pears, lemons, oranges, etc.

A national school of domestic arts for women, patterned after the Swiss schools of domestic science, has been founded in the City of Mexico by the department of public instruction.

**Cambridge University.**—A proposal to establish an institute of agricultural mechanics has been formally approved by the university senate. It is proposed to establish this institute in connection with the schools of engineering and agriculture with financial support from the Development Fund. The employment of an engineer as director and an agriculturist as an assistant director has been authorized.

**Amsterdam Colonial Institute.**—According to a note in *Nature*, there has been a movement in progress in Holland for the establishment of a colonial institute in Amsterdam commensurate with Dutch colonial interests, and adequately representative of the important part which Holland has taken in the prosecution of research in tropical agriculture and forestry. The promoters of the new institute have been able to secure the transfer of the economic collections, publications, and staff of a small but important colonial museum at Haarlem to the Amsterdam institute. The latter is at present housed in temporary quarters, but about \$643,200 is available for the construction of buildings and the installation of the new institute. It will apparently be supported mainly by subsidies from the government, the province of North Holland, and the city of Amsterdam, and by subscriptions from private individuals and firms. In 1914

the ordinary annual expenditure was \$36,582, but for 1915 the estimate was \$31,356, the reduction being due to war economies.

The present organization of the institute comprises three sections, viz, economic (which is practically the Haarlem museum transferred to new quarters), anthropological, and tropical hygiene. A site for the new buildings has been secured on the Oosterbegraafplaats, where a building to house the administrative offices and the economic and anthropological sections will be erected. A special building for the section of tropical hygiene will be constructed as a part of the buildings of the Hygienic Institute of the University of Amsterdam, with which this section will work in close cooperation. The institute has issued a number of publications, including a concise history by Dr. Sirks of research in natural science in the Dutch East Indies in *Koloniaal Instituut te Amsterdam, Mededeeling, No. VI. Afdeling Handels-museum, No. 2.*

**Necrology.**—Charles A. Muntz, the distinguished French agricultural chemist, died recently at the age of 71 years. He was widely known for his studies on air, soil, and agricultural products generally. Professor Muntz was of Alsatian birth and began his scientific career with Boussingault. His first important work was in connection with Schloessing in 1878, showing the biological nature of nitrification. Subsequently he made additional studies of nitrification, as well as working on mannit and other sugars and the nutrition of animals. He was the author of many scientific articles, a treatise on manures, etc.

The death in January is reported of Professor J. B. Auguste Chauveau, noted for his researches in comparative physiology and pathology, at the age of 90 years. Professor Chauveau's pathological work dealt mainly with the nature of contagion and viruses. He was especially well known as a physiologist, notably for work in glycogenesis and sugar utilization. He was one of the founders of *Journal de Physiologie et Pathologie Général*, and the author of the well known treatise on the Comparative Anatomy of the Domesticated Animals.

George Massee, mycologist and head of the cryptogamic department at the herbarium of the Royal Botanic Garden, Kew, until his retirement in 1915, died February 17, aged 67 years. He had been a frequent contributor on mycological subjects for many years.

**Miscellaneous.**—The home economics subsection of the Association of American Agricultural Colleges and Experiment Stations has appointed a committee to investigate the status of research in home economics at these institutions. The committee consists of Miss Louise Stanley, University of Minnesota; Miss Amy L. Daniels, University of Wisconsin; Miss Edna N. White, Ohio State University; Miss Ruth Wheeler, University of Illinois; Dean Mary E. Sweeny, University of Kentucky; and Dr. C. F. Langworthy, U. S. Department of Agriculture.

Sir Arthur Lee has been appointed director general of food production in Great Britain, Hon. E. G. Strutt, scientific technical expert, and A. D. Hall, agricultural adviser. A. D. Hall has also been appointed permanent secretary to the Board of Agriculture and Fisheries, vice Sir Sidney Olivier resigned.

The fifth annual conference of the American Association of Agricultural College Editors will be held at Cornell University, June 28 and 29.

## CONTENTS OF VOL. 36, NO. 8.

---

Editorial notes:	Page.
The Federal Aid Vocational Education Act.....	701
Recent work in agricultural science.....	710
Notes.....	796

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The chemical constitution of starch.—A review, Thomas.....	710
Further notes on the essential oils of Australian Myrtaceae.....	710
Distribution of nitrogen in coagulum and serum of <i>Hevea latex</i> , Eaton and Day..	710
Silage and silage fermentation, Lamb.....	710
Philippine beeswax, Brill and Agcaoili.....	711
Relation between the toxicity and volatility of creosote oils, Bateman.....	711
The sulphonphthalein series of indicators, Lubs and Acree.....	711
Some comparisons of methods for determining nitrogen in soils, Latshaw.....	711
Total carbon in soil by wet combustion, Schollenberger.....	711
Analyses of fertilizer samples taken with different samplers, Carpenter.....	711
The action of mineral acids on natural phosphate, Kazakov.....	711
The decomposition of calcium phosphate by acetic acid, Chirikov and Khardin.	712
Extraction of phosphoric acid from phosphorite, Kochetkov and Koblikov....	712
Extraction of phosphoric acid from natural phosphates, II, Kazakov.....	712

	Page.
The preparation of phosphate precipitate, Shvetsov.....	712
The determination of phosphorus pentoxid after citrate digestion, Smith.....	713
On the composition and solubility of acid calcium carbonate, Cavazzi.....	713
Determination of water in plant substances, Lebedfantsev and Zalygin.....	713
Method for the determination of galactose, van der Haar.....	713
A thermostat for the flour-testing laboratory, Bailey.....	714
Determination of hydrocyanic acid in string beans (haricots), Guignard.....	714
Separation and identification of food-coloring substances, Mathewson.....	714
A modification of Price's method for the separation of coal-tar dyes, Estes.....	714
The determination of butter fat in margarins, Jorgensen.....	715
Determination of water-soluble arsenic in lead arsenate, Gray and Christie....	715
An oxalate-iodid process for Paris green analysis, Peters and Fielding.....	715
Analysis, purification, and some chemical properties of agar agar, Fellers....	716
Analytical methods used in sugar chemistry, Saillard.....	716
Solubility of calcium sulphite in water and in sugar solution, van der Linden..	716
Sweet wines of high alcohol content without fortification, Cruess et al.....	716
Preparation and conservation of fruit juices in the United States, Truelle....	717
The canning of fruits and vegetables, Zavalla.....	717
The fruit-pulp industry, Blin.....	717
Honey vinegar, Bartholomew.....	717
Meat preservation on the farm, Marshall.....	717

## METEOROLOGY.

Daytime and nighttime precipitation and their economic significance, Kincer..	717
Slope and valley air temperatures, Blair.....	718
Anticyclones of United States and their movements, Bowie and Weightman..	718
Graphic method of representing and comparing drought intensities, Munger...	718
Frequency curves of climatic phenomena, Tolley.....	718
Monthly Weather Review.....	718
Climatological data for the United States by sections.....	719
Meteorological observations at Massachusetts Station, Ostrander and Saunders..	719
[Meteorological observations], Seeley.....	719

## SOILS—FERTILIZERS.

Measurement of inactive moisture in soil by dilatometer method, Bouyoucos..	719
The soil solution, how it is obtained, its composition and use, van Zyl.....	720
Methods of mechanical study of soils, Hissink.....	720
Reconnaissance soil survey of San Francisco Bay region, Holmes and Nelson..	721
Soil survey of Grant County, Indiana, Hurst et al.....	721
Soil survey of Starke County, Indiana, Grimes et al.....	721
Soil survey of Sioux County, Iowa, Smies and Bean.....	721
Soil survey of Ripley County, Missouri, Hutton and Krusekopf.....	721
Soil survey of Lamoure County, North Dakota, Anderson et al.....	722
Soil survey of Cambria County, Pennsylvania, Derrick et al.....	722
A soil survey of the proposed Palouse Irrigation Project, Holtz.....	722
Analyses of one hundred West Virginia soils, Bear and Salter.....	722
Reconnaissance soil survey of northeastern Wisconsin, Whitson et al.....	723
Reconnaissance soil survey of north-central Wisconsin, Whitson et al.....	723
Soil survey of Columbia County, Wisconsin, Whitson et al.....	723
Soil survey of Jefferson County, Wisconsin, Whitson et al.....	723
Notes on soils analyzed, Aston.....	723
Soils and crops of Nova Scotia.....	723
Terracing and drainage of hill soils by the "Kotak" system, Bleij.....	723
The importance of soil ventilation on the alluvium, Howard.....	724
Notes on the presence of nitrates in orchard soils, Gourley and Shunk.....	724
Effects of oxygen and CO <sub>2</sub> on nitrification and ammonification, Plummer....	724
Cause of disappearance of coumarin, vanillin, pyridin, and quinolin, Robbins..	725
The formation of soda in the soil, Bobko.....	725
Loss of fertilizers by leaching, Collison and Walker.....	725
[Use of manures in Germany], Middleton.....	726
Some effects of soluble humus on the growth of plants, Bottomley.....	726
Availability of nitrogenous fertilizers in an arid soil, Lipman and Gericke....	726
Ammonifiability <i>v.</i> nitrifiability as test for availability, Lipman and Burgess..	726
Technological-chemical research on superphosphates, Pratolongo.....	726
The preparation of superphosphate from phosphorites, Koblikov.....	727

	Page.
The solubility of slowly soluble phosphates in citric acid, Aita.....	727
Valuation of water-soluble <i>v.</i> citrate-soluble phosphoric acid, Pranke.....	727
The Garrison and Philipsburg phosphate fields, Montana, Pardee.....	728
[Biotite, phonolite, and similar substances as sources of potash], Chirikov.....	728
Blast-furnace slag as a source of bases for acid soils, Ames.....	728
The fertilizer value of city waste.—I, Garbage, O'Brien and Lindemuth.....	728
Commercial fertilizers, 1916, Woods et al.....	728
Analysis of fertilizers for 1916, Curry and Smith.....	729

## AGRICULTURAL BOTANY.

Experimental studies in the physiology of heredity, Blackman et al.....	729
The calculation of linkage intensities, Emerson.....	729
Morphology and evolution of leaves, Cook.....	729
The nature and distribution of the statolith apparatus in plants, Prankerd....	729
The influence of gaseous pressure on growth, McLennan.....	730
Transformation of pigments of plastids in living tissues of plants, Ljubimenko..	730
The mechanism of photosynthesis, Rikhter (Richter) and Kollegorskaja.....	730
The distribution of reducing sugar in beets, Pellet.....	731
Studies upon the maturity of grains.—I, Blagovfeshchenskii (Blagovesenskij). [Report of the research assistant in plant physiology], Hibbard.....	731 731
On the interpretation of the results of water-culture experiments, Stiles.....	731
The effect of vanillin and salicylic aldehyde in culture solution, Skinner.....	731
Antagonism of manganese and iron in growth of wheat, Tottingham and Beck.	731
Electromotive phenomena in plants, Waller et al.....	732
The effect of electrical stimulus on the permeability of plant cells, Koketsu...	732
The influence of defoliation on the development of sugar beet, Pellet.....	732
The effect of insecticides on flowering plants, Shreiber (Schreiber).....	733
Snow cracks on trees as an indication of the amount of bending, Maekawa....	733
The ecological significance of soil aeration, Cannon and Free.....	733
Distribution of cacti with reference to soil temperature and moisture, Cannon..	733
Osmotic pressure in roots and leaves of plants, Il'in (Iljin) et al.....	733
Transpiration and assimilation in steppe plants, Il'in (Iljin).....	734
Teratological notes.—I, Abnormal seedlings, Hardy.....	734
Identity of cohoba, the narcotic snuff of ancient Haiti, Safford.....	734
A fungus producing hydrocyanic acid and benzoic aldehyde, Guyot.....	734

## FIELD CROPS.

Report of division of farm crops, Shoesmith and Spragg.....	734
[Field crop experiments], Watts.....	735
Report on field experiments, 1914, Wilson and Smith.....	735
Fall-sown grains in Maryland and Virginia, Stanton.....	735
Seed-flax production, Clark.....	736
Change of sex in hemp, Pritchard.....	736
Rice variety studies, van Drent.....	737
[Sugar cane].....	737
Breeding sugar cane.....	737
Studies in Indian sugar canes.—II, Sugar-cane seedlings, Barber.....	737
Production of sugar in the United States and foreign countries, Elliott.....	737
Manuring of swedes with different phosphatic manures; purchase of basic slag..	738
Manuring of swedes with different phosphatic manures.....	738
The suppression of characters on crossing, Biffen.....	738
Work in connection with Egyptian wheat, Dudgeon and Bolland.....	739
Carman's wheat-rye hybrids, Leighty.....	739
Seed reports, 1914, 1915, Kellogg and Gensler.....	739
Results of seed tests for 1916, Taylor and Prince.....	739
Michigan weeds, Beal.....	739
Kill garlic and wild onion by oil spraying, Selby and Van Atta.....	740
Eradication of bracken.....	740
Improvement of hill and peaty pastures; eradication of bracken.....	740

## HORTICULTURE.

On the problem of extra root nutrition and treatment of trees, Ljubimenko...	740
The relation of humidity to the ripening and storage of fruits, Shamel.....	741
Statistics of fruits in principal countries, Ruddiman.....	741
Minnesota State Fruit-Breeding Farm in 1916, Haralson.....	741

	Page.
Report on the Imperial Nikitsky Orchard in 1912.....	741
Apple growing.....	741
The apple in Canada, its cultivation and improvement, Macoun.....	741
Harvesting, packing, and marketing the apple crop, Mason.....	742
Sending apples by parcel post, Thayer.....	742
The native pears of North Africa, Trabut.....	742
Problems and opportunities in the fig industry, Coit.....	742
Statistics on the production of grapes in 1916.....	742
Tropical pomology.—A new field for horticulturists, Popenoe.....	742
The navel orange of Bahia; notes on Brazilian fruits, Dorsett et al.....	743
The use of commercial fertilizers, Breazeale.....	743
The pomegranate, Hodgson.....	743
Planting pecans, budding, grafting, and transplanting pecan trees, Evans.....	743
Profitable herb growing and collecting, Teetgen.....	743
Poppy culture and the production of opium in Valladolid, Benaiges de Aris.....	743
The dahlia, Peacock.....	743
Parks: Their design, equipment, and use, Burnap.....	743
The food garden, Rowles.....	743
From garden to pantry, De Lissa.....	744
Vegetable growing, Boyle.....	744
Report of bureau of insecticides and fungicides for 1915, Johnson et al.....	744

## FORESTRY.

Forest terminology.....	744
The situation, Fernow.....	744
Sixth biennial report of the state forester of California, Homans.....	744
Biennial report of the forestry commission for 1915-16, Brown et al.....	744
Division of forestry and parks, Moody.....	744
Continuous forest production of privately owned timber lands, Kirkland.....	744
Farm woodlot timber: Its uses and principal markets, Lamb.....	745
Trees planted by new machine replace railway snow fences, Smith.....	745
The Christmas tree industry, Secrest.....	745
The greenheart of commerce, Mell.....	745
True mahogany, Mell.....	745
Contribution to the knowledge of red quebracho, Galarza.....	745
Lumbering in the sugar and yellow pine region of California, Berry.....	745
Annotated list of the forest trees of the Hawaiian archipelago, MacCaughy.....	745
British-grown timber and timber trees, Webster.....	746

## DISEASES OF PLANTS.

[Report of the research assistant in plant pathology], Coons.....	746
[Plant diseases in Uganda, 1915], Fyffe.....	746
Phytopathological work in the Tropics, Johnston.....	746
Heteroecism of <i>Peridermium harknessii</i> and <i>Cronartium quercus</i> , Fromme.....	746
Studies of the genus <i>Phytophthora</i> , Rosenbaum.....	747
Mechanism of tumor growth in crown gall, Smith.....	747
Intoxicating bread, Naumov.....	747
Glume rust of wheat, Berthault.....	747
Crown gall of alfalfa in France, Arnaud.....	747
Diseases of asparagus and of melon, Arnaud.....	748
Fungus and bacterial diseases of clover, Iachevskii (Jaczewski).....	748
A new disease of the flowers of red clover, Bondartsev (Bondarzew).....	748
Relation of soil temperature to infection of flax by <i>Fusarium lini</i> , Tisdale.....	748
[Report of the assistant in plant pathology], Muncie.....	748
Celery leaf spot.....	748
A collar disease of pea, Guéguen.....	749
Reappearance of <i>Phytophthora infestans</i> during growth of potato, Eriksson.....	749
A Melanconium parasitic on the tomato, Tisdale.....	749
A parasitic saccharomycete of the tomato, Schneider.....	749
A note on <i>Phytophthora infestans</i> occurring on tomatoes, Wiltshire.....	749
Spraying and dusting tomatoes, Fromme and Thomas.....	750
Dusting and spraying nursery stock, Stewart.....	750
A black rot of apples, Spinks.....	750
A spot disease of apples, Barker.....	750
Fungus and other diseases of stone fruits, Darnell-Smith and Mackinnon.....	750

	Page.
Plum diseases, Rabaté.....	751
Comparative tests with fungicides against grape downy mildew, Caruso.....	751
Second series of tests with fungicides against grape downy mildew, Caruso....	751
A bacterial disease of the gooseberry, Barker and Grove.....	751
A new remedy for American gooseberry mildew, Barbarin.....	751
Studies on diseases of mulberry in 1913, Arnaud and Secrétain.....	751
"Canker" and "dieback" disease of mulberry, Salmon and Wormald.....	751
Eelworm in daffodils, Bliss.....	752
Leaf spot rot of pond lilies caused by <i>Helicosporium nymphæarum</i> , Rand.....	752
Studies on chestnut tree diseases, Ducomet.....	752
Black canker of chestnut and the restoration of the chestnut, Prunet.....	752
A method to induce sporulation in <i>Botryosphaeria berengeriana</i> , Matz.....	752
<i>Phacidium infestans</i> on western conifers, Weir.....	752
<i>Pinus ponderosa</i> and <i>P. jeffreyi</i> , hosts for <i>Razoumofskyia americana</i> , Weir.....	753
The occurrence of western red rot in <i>Pinus ponderosa</i> , Long.....	753

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Nematode parasites of Rodentia, Lagomorpha, and Hyracoidea, Hall.....	753
Diagnosis of plague in rats, Williams.....	753
Propagation of wild duck foods, McAtee.....	753
Report of the entomological department, Troop.....	753
Report of the south coast laboratory, Smyth.....	753
[Contributions from the phytopathological service at Wageningen].....	754
[Italian entomological communications].....	754
Pests of orange trees and other Aurantiaceæ, Bondar.....	754
On some animal pests of the Hevea rubber tree, Green.....	754
Entomophagous insects and their practical employment in agriculture, Berlese	754
Causes which affect toxicity of arsenicals employed in agriculture, Battail....	754
<i>Termes gestroi</i> as a pest of the Para rubber tree, Pratt.....	755
[Use of d'Herelle's bacillus in the control of <i>Schistocerca peregrina</i> ].....	755
The Tingitoidæ of Ohio, Osborn and Drake.....	755
Review of the Philippine Membracidæ, Funkhouser.....	755
The green bug or spring grain aphid ( <i>Toxoptera graminum</i> ), Bilsing.....	755
Elm leaf rosette and woolly aphid of the apple, Patch.....	755
White flies of the subfamily Aleyrodinæ (Aleyrodidæ), Quaintance and Baker.	755
The coccid enemies of the vine, Feytaud.....	755
The San José scale, Painter.....	755
Agricultural importance of mycosis of <i>Chrysomphalus dictyospermi</i> , Savastano.	755
Problems connected with <i>Gelechia gossypiella</i> , Gough.....	756
Note on a machine to kill <i>Gelechia</i> larvæ by hot air, Gough.....	756
Life history of codling moth in Pecos Valley, N. M., Quaintance and Geyer.	756
<i>Sorosporella uvella</i> and its occurrence in cutworms in America, Speare.....	757
On <i>Lestophonus</i> , a parasite of cottony cushion scale, Smith and Compere.....	757
Observations on the life history of <i>Pterodontia flavipes</i> , King.....	757
Anopheles infectivity experiments, Mitzmain.....	757
Wireworm control, French.....	758
Powder-post damage by Lyctus beetles to hardwood, Hopkins and Snyder..	758
Foul brood regulations, Paddock.....	758
The Texas foul brood law and foul brood regulations, Paddock.....	758
The Cresson types of Hymenoptera, Cresson.....	759
<i>Tetrastichus bruchophagi</i> , a parasite of <i>Bruchophagus funebris</i> , Urbahns.....	759
Note on <i>Rhogas kitcheneri</i> , Gough.....	759
The egg and early development in some hymenopterous parasites, Silvestri....	759

## FOODS—HUMAN NUTRITION.

Changes in fresh beef during cold storage above freezing, Hoagland et al.....	759
Eggs and their value as food, Langworthy.....	761
Practical milling tests, Ladd.....	761
The distribution of chlorin in cereals and dry legumes, Balland.....	761
Recipes for the preparation of the dasheen.....	761
[Food and drug inspection], Ladd and Johnson.....	662
Eighth annual report of the board of food and drug commissioners.....	762
Report of the Dairy and Food Department [of Iowa], Barney.....	762
A summary of the market situation in Boston, Cherington et al.....	762

	Page.
Education in economy [of foods], Spooler.....	762
Planning of meals, McGuire.....	762
Misguided appetite and the high cost of living, Perkins.....	763
Electrical cooking and heating, Groves.....	763
[Report of the] nutrition laboratory, Benedict.....	763
On the rôle of organic acids in the process of peptic digestion, Belgowsky.....	763
Pellagra.....	763
Studies in pellagra.....	763
The production in dogs of human pellagra, Chittenden and Underhill.....	764

## ANIMAL PRODUCTION.

Palm kernel cake, Crowther.....	764
Commercial feeding stuffs, Patten, Berger, Smoll, and De Windt.....	765
Commercial feeding stuffs, 1915-16 [and] Texas feed law, Youngblood.....	765
Sheep husbandry in Oklahoma, Carlyle and Spencer.....	765
Sheep husbandry in the Pacific Northwest, Hislop and Howell.....	766
Experiments in disposal of irrigated crops through the use of hogs, Holden.....	767
Fattening swine on rice by-products, Dvorachek et al.....	768
Breeds of swine, Ashbrook.....	769
How to select a sound horse, Reese.....	769

# EXPERIMENT STATION RECORD.

VOL. 36.

JUNE, 1917.

No. 8.

---

In the passage of the Federal Aid Vocational Education Act another important step has been taken by the Federal Government in its relations to education. Under the new measure, federal appropriations ultimately aggregating over \$7,000,000 per annum have been made available for cooperation with the States in the promotion of vocational education in agriculture, the trades and industries, and home economics, including the preparation of teachers. The principle of federal aid through the States to education in institutions of subcollegiate grade has been established, and an additional set of administrative machinery has been devised to operate the new system of education which is provided.

As a pioneer measure, the new legislation inevitably recalls the original Morrill Act. Primarily both laws were apparently intended to provide training in agriculture and the industries, the one in collegiate, the other in subcollegiate, institutions. They were thus both designed to develop a type of education of the utmost importance to our country, but previously never directly supported by the Federal Government and to only a limited degree by the States and local communities. Likewise both acts involved the introduction of a new system of education into the existing system.

It is somewhat remarkable that these two measures, separated in time by a period of over half a century, should both have been enacted in a period of great national crisis. The Morrill Act of 1862 was of course signed in the midst of the Civil War, while the Vocational Education Act of 1917 antedated by only a few weeks the formal entrance of the United States into the present conflict. The coincidence is the more striking since both measures were designed to foster agriculture and the industries, foremost among the arts of peace, and since both had been pending in Congress for years before the outbreak of hostilities.

Early in 1907 a bill was introduced into the House of Representatives by Hon. Charles R. Davis of Minnesota, providing annual federal appropriations for industrial education in agricultural high schools and in city high schools. In a speech a few weeks later, explaining the bill, Mr. Davis said, "It is mainly for the purpose of

encouraging the type of education for the mass of our people which will train them for the practical affairs of life. . . . It proposes that we give our workers a square deal, by giving them a chance to secure technical training as we now provide technical training for the professional classes."

This bill differed widely as to details from the measure eventually enacted. It contained a plan for the maintenance of branch experiment stations and made no provision for the training of teachers. Subsequently it was reintroduced into later sessions of Congress, as were also a considerable number of other bills having in view the same purpose of fostering secondary education in agriculture, the mechanic arts, and home economics. One of these, introduced by the late Senator J. P. Dolliver of Iowa, which also included provisions for teacher training in vocational subjects at State normal schools and extension work in agriculture at the colleges of agriculture, received a favorable report from the Senate Committee on Agriculture and Forestry in 1910.

An elaborate measure, introduced in 1912 by Senator Carroll S. Page of Vermont and embodying substantially the same objects as the bill just mentioned, was likewise favorably reported by the Senate committee, and in 1913 this measure with some modifications was substituted by the Senate for the text of an agricultural extension bill which had passed the House. No agreement was reached between the two Houses, however, as regards these measures before the adjournment of that Congress.

In 1914 the appointment was authorized of a commission to study the entire question of national aid for vocational education. This commission, of which Senator Hoke Smith of Georgia was chairman, submitted an extended report later in the year, as previously noted in these pages (E. S. R., 31, p. 402). It advocated a system of schools of subcollegiate grade for pupils over 14 years of age, stating that "the most opportune time to train the boy is during his adolescent period, when he has already gained much knowledge of farm work and its requirements, and is at the age when he is most ambitious, most alert, and therefore most teachable." It laid much stress on the desirability of directed or supervised farm practice, and considered as fundamental the necessity of providing facilities for the adequate preparation of teachers.

Endorsements for the principle of federal aid for vocational education, few in number at first, had been steadily accumulating during the years the question was under consideration. The National Society for the Promotion of Industrial Education, the National Education Association, the National Grange, the American Federation of Labor, the American Home Economics Association, and the International Congress of Farm Women may be cited as types of the many

organizations which at various times signified their approval of the general policies involved.

The subject is naturally one of intimate concern to the land-grant colleges, and had been prominently before the Association of American Agricultural Colleges and Experiment Stations on a number of occasions, notably at Washington, D. C., in 1910 and at Columbus, Ohio, in 1911. At the Washington meeting it will be recalled the association declined to commit itself upon the proposition, but in 1911, when considerable modification had been proposed, a motion was adopted favoring "federal aid for public schools of secondary grade, providing secondary education in agriculture, home economics, the trades and industries, including manual training, and for the education and professional training of teachers for these schools in the several States as may be determined by the legislature." The association also declared its belief that legislation to this end should be "in harmony with the Morrill and Hatch Acts, preserving the autonomy of the several States in the distribution of funds and in the administration of secondary education as now provided in the case of the agricultural colleges and experiment stations."

The measure ultimately adopted was introduced into the Sixty-fourth Congress by Senator Hoke Smith on December 7, 1915, and was passed by the Senate with amendments July 31, 1916. Its early enactment was strongly urged by President Wilson in addressing Congress at its reopening in the following December, as "of vital importance to the whole country because it concerns a matter too long neglected, upon which the thorough industrial preparation of the country for the critical years of economic development immediately ahead of us in very large measure depends . . . . It contains plans which affect all interests and all parts of the country, and I am sure that there is no legislation now pending before the Congress whose passage the country awaits with more thoughtful approval or greater impatience to see a great and admirable thing set in the way of being done."

In January, 1917, the bill passed the House, with amendments substituting the text of a somewhat similar bill previously introduced by Hon. D. M. Hughes of Georgia. After a period in conference for the adjustment of differences, the most important of which related to the composition of the administrative board, the status of home economics instruction, and the manner of providing the appropriations, a complete agreement was reached and the new law was signed by President Wilson on February 23, 1917.

As an expression of educational policy, the new act embodies some important departures from previous legislation. It makes provision for the training within the schools of a large group of our popula-

tion hitherto unreached directly by the Federal Government. On the one hand, by offering instruction along vocational lines and of sub-collegiate grade, it supplements the Morrill Act, the expressed purpose of which is to maintain colleges "to teach such branches of learning as are related to agriculture and the mechanic arts . . . in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life." On the other hand, since it contemplates a system of training in the schools, it also supplements the Agricultural Extension Act of 1914, in which the service provided is "the giving of instruction and practical demonstrations in agriculture and home economics to persons not attending or resident in state colleges in the several communities." Since it imposes definite requirements as to the training of teachers, it also represents a material extension of authority over the purely permissive provisions of the Nelson Amendment of 1907.

The principle of extending financial aid to education through the States rather than by direct appropriations to institutions is again adhered to, as is also that of requiring expenditures by the States or local communities on a dollar-for-dollar basis. The States may, however, if they desire, accept the benefits of the act only for agriculture or for the trades and industries, thereby receiving funds and assuming obligations accordingly. It would thus be unnecessary for States desiring federal appropriations only for vocational training in the trades and industries to maintain a system of vocational training in agriculture, or vice versa. This feature is of course quite different from the provisions of the Morrill Acts, which contemplate for each State the maintenance of instruction in both the mechanic arts and agriculture, and attempt no division of funds between the two branches.

The most radical innovation in the act deals with the method of its administration. Previous legislation along these lines has regarded the college of agriculture and mechanic arts as the state unit, whether for college instruction under the Morrill Acts and acts supplementary thereto, the preparation of teachers under the Nelson Amendment, the conducting of research in agriculture under the Hatch and Adams Acts, or the carrying on in cooperation with the U. S. Department of Agriculture of extension work in agriculture and home economics under the Extension Act. The administration of those measures dealing with college instruction has centered in the Department of the Interior, and of those dealing with research and extension work in agriculture in the Department of Agriculture. The vocational education act in both respects establishes a new administrative system.

As its head there is provided a Federal Board for Vocational Education. This board is to consist of seven members, including the Secretaries of Agriculture, Commerce, and Labor, and the U. S. Commissioner of Education, *ex officio*, with three members to be appointed by the President and confirmed by the Senate, ultimately for terms of three years each. One of the appointed members is to be a representative of the manufacturing and commercial interests, one of the agricultural interests, and the third of those of labor. The board is to select its own chairman each year.

The Federal Board is charged with the administration of the act, the details as to the care of funds, the certifying of the States, etc. in general plan resembling the legislation for the agricultural colleges and experiment stations. In addition it is empowered to make, or have made, investigations and reports to aid the States in the establishment of vocational schools and classes and in giving instruction in agriculture, the trades and industries, commerce and commercial pursuits, and home economics. These studies are to include agriculture and agricultural processes and the requirement upon agricultural workers, similar studies as regards the trades, industries, and commerce, home management, domestic science and the study of related foods, and the principles and problems of administration of vocational schools and of courses of study and instruction in vocational subjects. In the discretion of the board, the studies concerning agriculture may be made in cooperation with or through the Department of Agriculture. Similar cooperative arrangements may be made with the Departments of Labor and Commerce for industrial subjects, while the studies of the administration of vocational schools, curricula, and methods of instruction in vocational subjects may be taken up in cooperation with or through the Bureau of Education. An appropriation of \$200,000 per annum, available from the date of passage of the act, is made to the board for its expenses.

To cooperate with the Federal Board in carrying out the act, each State when accepting its provisions is to designate a state board of at least three members. The state board of education or some board having charge of the administration of public education or of any kind of vocational education may be designated as the state board, or an entirely new board may be created.

The state board is to prepare plans for the approval of the Federal Board, showing the details of the work for which it is expected to use the appropriations. These plans, it is specified, must show the kinds of vocational education contemplated, the kinds of schools and equipment, courses of study, methods of instruction, and the qualifications and the plans for the training of the teachers and agricultural supervisors. In all cases the work must be conducted under public supervision and control.

The plans of expenditures for salaries in agricultural subjects must in addition show that the controlling purpose of the education is to fit for useful employment, that the training is less than college grade, and that it is designed to meet the needs of persons over 14 years of age who have entered upon or who are preparing to enter upon the work of the farm or of the farm home. The State or local community must provide the necessary plant and equipment, including a school farm or other farm for use in at least six months of supervised practice in agriculture per year, as well as contribute one-half the expenditure for the salaries of the agricultural teachers and supervisors, and bear the entire cost of all supplementary instruction.

The requirements are very similar as regards expenditures for salaries of teachers of trade, home economics, and industrial subjects, except that no provision is made for the federal payment of salaries of supervisors or directors in these branches. Practical work in these subjects is required for those not already employed, and there are also provided part-time classes in subjects "to enlarge the civic or vocational intelligence of workers over 14 and less than 18 years of age," and evening industrial schools which "confine instruction to that which is supplementary to the daily employment."

The training of teachers and supervisors is restricted to persons who have had adequate vocational experience or contact in the line of work for which they are preparing themselves, or are acquiring such qualifications as a part of their training. The federal appropriations for teacher training must be divided among agricultural, trade and industrial, and home economics subjects, no one of these subjects being granted more than 60 nor less than 20 per cent of the State's allotment for that year. After June 30, 1920, federal appropriations for salaries in either agriculture or in the industrial subjects can not be utilized unless the State is providing for teacher training in these lines.

The federal appropriations to the States are divided into three distinct groups, providing respectively for the payment of salaries of teachers, supervisors, or directors of agricultural subjects; for the payment of salaries of trade, home economics, and industrial subjects; and for the preparing of teachers, supervisors, or directors of agricultural subjects, and of teachers of trade and industrial and home economics subjects. The allotment in each of these groups begins with the fiscal year ending June 30, 1918, the amounts increasing for several years to a permanent maximum.

The main initial appropriation for salaries in agricultural subjects is \$500,000. This is increased by \$250,000 per annum during the next six years and then by \$500,000 per annum during the next two years, making an appropriation of \$3,000,000 for the fiscal year 1926 and

annually thereafter. Corresponding appropriations are made for the payment of salaries in the industrial subjects, but it is provided that no more than 20 per cent of these appropriations may be used for the instruction in home economics. The main appropriation for preparing teachers and supervisors is likewise \$500,000 for the first year, but increases to \$700,000 and \$900,000 respectively for the next two years and then becomes \$1,000,000 per annum thereafter.

The basis of allotment to the States also varies with the different groups. For salaries of the school instruction staff, the basis for each State is, for agriculture, the proportion which its rural population bears to the entire rural population of the country; for the industrial subjects, the corresponding proportions of the urban populations; and for the appropriation for preparing teachers and supervisors, the relative proportions of the total populations of the State and the Nation.

Provision is also made, however, whereby each State, regardless of its population, may receive at least \$5,000 per annum from each fund, and ultimately at least \$10,000. In order to provide this minimum allotment, small supplementary appropriations are granted, totaling for the entire country, when the system is in full operation, \$27,000 per annum for salaries of the agricultural instruction staff, \$50,000 for salaries of the industrial group, and \$90,000 for teacher preparation. Assuming that these sums are utilized in full and that the States accept the act in its entirety, the ultimate permanent appropriations under the act, including the maintenance fund for the Federal Board, may aggregate \$7,367,000 per annum.

As finally passed, this act embodies a system of federal and state administration of vocational education which is a compromise between the views of those who thought a separate system of public education should be organized for vocational purposes and those who believed that the unity of our present public school system should be maintained. While a separate Federal Board has been created it is closely linked with the Bureau of Education, which deals with the whole public school system. Each State is left free to establish a separate system or to make the vocational schools and courses a part of its existing system. It is therefore probable that different plans will be adopted in the different States, and that thus there will be many experimental efforts to solve the problems of vocational education.

Thus far, vocational education on a broad scale has been attempted only in the older countries, where class distinctions have made it comparatively easy to fix the industrial, and to a great extent the social, status of the youth at a comparatively early age. There it

has seemed best to organize the vocational schools on such a basis as would practically prevent the passage of students to institutions of higher learning. The needs of certain industries have been the paramount considerations in determining the courses of instruction in the vocational schools. Matters relating to the general education of the students for citizenship or for social life have in consequence been little regarded, and industrial efficiency has been almost the sole standard for measuring the results of the work of these schools. Without doubt much success on this basis has been attained, but it remains as yet an open question whether such education is a sufficient preparation for life in a free democracy. On the other hand there is danger that the traditional views and methods which have hitherto prevailed in our public school system may so influence the attempts to establish vocational education in this country that such education may be too amateurish and unpractical.

It is, therefore, probably very fortunate that so much flexibility of organization has been incorporated in this act. This broad measure, which will affect the educational system of our vast country with its great variety of industrial conditions and possibilities, gives an unequalled opportunity for the study and trial of curricula, methods of teaching, practical work, equipment, etc., adapted to a wide range of vocations and very diverse environments.

The training of the teachers provided for will throw a very heavy burden of responsibility on our higher technical institutions and particularly the land-grant colleges. These institutions have been very successful in training technical experts who have contributed in large measure to the success of our industries. They have not as yet paid any large attention to the training of teachers for secondary schools of the strictly vocational type. The pedagogy of this class of education is yet in its preliminary stages. It evidently will not do simply to copy what has been worked out abroad. There is therefore great incentive for men of original thought and inventive skill to enter this comparatively new field of teacher training. The colleges should offer inducements to able men to undertake this service, and use every proper means to build up strong educational departments along this line.

Since the Federal Board is charged with the approval of the plans proposed by the state authorities, as well as with the general administration of the measure, it is quite probable that the policies which the board may formulate will be an important factor in getting the new system of education under way. Opportunity is also afforded for the board to render constructive service of wide value through the educational studies for which provision is made.

At the time of writing, the appointive members of the Federal Board have not been announced, so that organization of this body

has not been affected. Acceptances of the act, however, are being considered in various States, and in a number the assent of the legislatures has already been obtained. For several reasons, it can hardly be expected that a system of this size and complexity can be put into complete operation immediately, and a program of gradual development is, indeed, contemplated in the increasing scale of allotments carried in the act itself. Progress under its provisions, however, seems likely to be awaited with unusual public interest, especially at this time when attention is being focused as never before upon all that pertains to agricultural and industrial efficiency as an element of national preparedness.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The chemical constitution of starch.—A review, A. W. THOMAS (*Biochem. Bul.*, 4 (1915), No. 14-15, pp. 379-397, figs. 4).—This is a general review and discussion of the work on the constitution of starch. A list of 29 references to the literature cited is included.

Further notes on the essential oils of Australian Myrtaceæ (*Proc. Roy. Soc. Victoria, n. ser.*, 28 (1915), No. 1, pp. 149-156, fig. 1).—Three papers are included.

I. *The essential oil of Eugenia smithii*, A. E. Dawkins (pp. 149-152).—The oil distilled from the leaves was of a pale yellow color and possessed a sweet, penetrating odor. The physical constants were determined in May, 1914, with the following results: Percentage yield, 0.44; specific gravity at 15° C., 0.866; optical rotation at 15°, +35°; refractive index at 20°, 1.4701. In July of the same year the following constants were obtained: Percentage yield, 0.28; specific gravity, 0.863; optical rotation, +34.6°; refractive index, 1.4675. The results indicate a slight seasonal variation. Chemical examination showed the oil to have the following percentage composition: *d-a*-pinene, from 80 to 90; esters, 4; and alcohols, 3.7.

II. *The calculation of the oil content of foliage from measurements of the number and size of the oil glands*, A. E. Dawkins (pp. 153, 154).—A formula for calculating the approximate yield of oil from oil-producing plants is submitted and its use described in detail.

III. *The essential oil of Eucalyptus platypus*, J. C. Earl (pp. 154-156).—A yield of about 1 per cent of oil was obtained by distillation of the fresh leaves. It yielded the following constants: Specific gravity at 15°, 0.9045; optical rotation at 12°, +9.1°; refractive index at 20°, 1.4675; saponification number, 6; saponification number after acetylation, 24; cineol determined by direct absorption with resorcin, 59 per cent by weight. No aldehydes or ketones were present.

Further examination revealed the following percentage composition of the oil: Pinene, from 20 to 25; phellandrene, from 10 to 15; cineol, from 55 to 60; aromadendrene, from 10 to 15; and alcohols, free and combined as esters, 5.

The distribution of nitrogen in coagulum and serum of *Hevea latex* on coagulation with acetic acid, B. J. EATON and F. W. F. DAY (*Agr. Bul. Fed. Malay States*, 4 (1916), No. 11, pp. 350-353).—As the rate of vulcanization of *Hevea rubber* depends on the amount of some substance formed by the decomposition of the nitrogenous constituents of the latex after coagulation of the rubber, the authors determined the nitrogen contents of the various portions after coagulation, finding in the latex 0.11, the wet coagulum 0.15, and the serum 0.06 per cent by weight. The significance of the results is discussed in some detail.

Silage and silage fermentation, A. R. LAMB (*Iowa Sta. Bul.* 168 (1916), pp. 3-11).—This is a general discussion of the subject under the following topics:

The fermentation of silage, cause of silage fermentation, soft corn ear silage, rape silage, other silage crops, and general precautions to be observed in the preparation of corn silage.

Philippine beeswax, H. C. BRILL and F. AGCAOLLI (*Philippine Jour. Sci., Sect. A, 11 (1916), No. 1, pp. 15-18*).—The constants for a number of samples of Philippine beeswax, including the specific gravity at 15.5° C., melting point, saponification value, acid value, ester value, ratio number, iodine value (Hanus), unsaponifiable matter, and clouding point, are submitted in tabular form. Comparative analytical data of Japanese, Korean, and Philippine beeswaxes are also included.

The relation between the toxicity and the volatility of creosote oils, E. BATEMAN (*Jour. Indus. and Engin. Chem., 8 (1916), No. 12, pp. 1094, 1095, fig. 1*).

On the sulphonphthalein series of indicators and the quinone-phenolate theory, H. A. LUBS and S. F. ACREE (*Jour. Amer. Chem. Soc., 38 (1916), No. 12, pp. 2772-2784*).

Some comparisons of methods for determining nitrogen in soils, W. L. LATSHAW (*Jour. Indus. and Engin. Chem., 8 (1916), No. 12, p. 1127*).—The bumping during the distillation of ammonia in nitrogen determinations in soils was obviated by sufficient dilution of the mixture after the digestion. The heavy metals from the soils contained in the digest were considered to be the cause of the bumping, and it was found that where no mercury was used there was no bumping. The Gunning method proved satisfactory in respect to eliminating the bumping, but required considerable time for digestion, in some cases as much as four or five hours. The time of digestion, however, was reduced to an average of two and a half hours by the use of from 0.08 to 0.1 gm. of copper wire as catalyst.

The method for the determination of nitrogen in soils used at the Kansas Experiment Station is described in detail. Comparative analytical data show no marked differences between this method and the Official Method.

Total carbon in soil by wet combustion, C. J. SCHOLLENBERGER (*Jour. Indus. and Engin. Chem., 8 (1916), No. 12, p. 1126*).—The author, at the Ohio Experiment Station, considers the wet combustion volumetric method of Ames and Gaither (*E. S. R., 32, p. 805*) to be capable of yielding results which compare very favorably with those obtained from furnace combustion and gravimetric determinations. The changes suggested in the procedure consist of the use of a mixture of phosphoric and sulphuric acids, instead of sulphuric acid alone, with chromic anhydride as the oxidizing agent; the substitution of barium hydroxide for sodium hydroxide as the absorbent for carbon dioxide; and the replacement of the modified Camp absorption tube by Meyer's absorption apparatus or the bead tower described by Truog (*E. S. R., 34, p. 504*).

Comparative experimental data with the furnace combustion gravimetric procedure, the Parr method, and the old wet combustion volumetric method indicate the accuracy of the modified procedure.

Note on the results of analyses of fertilizer samples taken with different styles of samplers, F. B. CARPENTER (*Jour. Indus. and Engin. Chem., 8 (1916), No. 12, pp. 1144, 1145*).—Some analytical data are submitted which show the great variation in results of samples taken by several individuals with various forms of samplers from the same lot of homogeneous material carefully prepared. A form of sampler which closes was found to give results on ammonia nearest to the theoretical amount.

The importance of uniform methods of sampling fertilizers is indicated.

The action of mineral acids on natural phosphate, A. V. KAZAKOV (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk.*

*Khov. Inst.*, 10 (1914), pp. 38-50; *Izv. Moskov. Selsk. Khov. Inst. (Ann. Inst. Agron. Moscou)*, 22 (1916), No. 1, pp. 38-50.—The immediate transformation of natural calcium phosphate into the diphosphate by the action of small amounts of mineral acids was studied.

It is concluded that with the use of dilute aqueous or concentrated solutions of phosphoric acid or of pure or technical sulphuric acid there is a complete transformation into the dicalcium phosphate. The treatment with phosphoric acid yields a product which contains from 38 to 39 per cent of total phosphoric acid, 91 per cent of which is soluble. By the use of sulphuric acid the mixture of dicalcium phosphate and calcium sulphate obtained contains 23 per cent total phosphoric acid, 90 per cent of which is soluble.

Certain negative results were obtained in which the technical phosphoric acid did not decompose the phosphorite either into di- or monocalcium phosphate. This inactivity is being further studied.

On the decomposition of calcium phosphate by acetic acid, F. V. CHIRIKOV and N. V. KHARDIN (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, *Moskov. Selsk. Khov. Inst.*, 10 (1914), pp. 104-114; *Izv. Moskov. Selsk. Khov. Inst. (Ann. Inst. Agron. Moscou)*, 22 (1916), No. 1, pp. 104-114).—The authors studied the action of dilute acetic acid (2 per cent) on calcium phosphate. The transition of the phosphoric acid into the soluble state required 180 cc. of acetic acid in the case of  $\text{CaHPO}_4$ , and 540 cc. in the case of the  $\text{Ca}_2(\text{PO}_4)_2$ , for every gram of the salt.

Calcium carbonate lowers the amount of phosphoric acid soluble because it diminishes the amount of acid available for solution and also because of the introduction of a common ion. Sodium carbonate also lowers the  $\text{P}_2\text{O}_5$  content in the solution, the effect of such action being even greater than that of the calcium carbonate. Calcium acetate diminishes the amount of  $\text{P}_2\text{O}_5$  in the solution because of again introducing a common ion. The same effect is produced to a greater degree in the case of  $\text{CaHPO}_4$ , than in the case of  $\text{Ca}_2\text{PO}_4$ , by calcium nitrate.

Extraction of phosphoric acid from phosphorite, V. P. KOCHETKOV and N. P. KOBLIKOV (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, *Moskov. Selsk. Khov. Inst.*, 10 (1914), pp. 12-15; *Izv. Moskov. Selsk. Khov. Inst. (Ann. Inst. Agron. Moscou)*, 22 (1916), No. 1, pp. 12-15).—The authors have studied the influence of the quantity of sulphuric acid in regard to its concentration, the manner of moistening the phosphate, the temperature, the time of treatment, and stirring in the extraction of phosphoric acid from the natural rock. The data are submitted in tabular form.

Extraction of phosphoric acid from natural phosphates.—II, The influence of the construction of the stirring apparatus and its speed, A. V. KAZAKOV (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, *Moskov. Selsk. Khov. Inst.*, 10 (1914), pp. 1-11, figs. 15; *Izv. Moskov. Selsk. Khov. Inst. (Ann. Inst. Agron. Moscou)*, 22 (1916), No. 1, pp. 1-11, figs. 15).—Continuing previous work (E. S. R., 34, p. 329), a detailed study of the various types of stirring apparatus in general use and the effect of the rate of speed on the extraction of the acid from mineral phosphates is described.

The Gatterman type of apparatus yielded the most satisfactory results. The effect of the speed was found to depend on certain variables, such as the absolute and relative dimensions of the stirrer, the capacity of the vessel containing the material which was being stirred, the viscosity of the mixtures, etc. It is indicated that the fixing of a definite rate of speed is simply empirical, and may be modified in accordance with the variables.

The preparation of phosphate precipitate, K. N. SHVERTSOV (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, *Moskov. Selsk. Khov. Inst.*, 10

(1914), pp. 23-37; *Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 22 (1916), No. 1, pp. 23-37).—The author has investigated the conditions best suited for the precipitation of phosphoric acid by calcium carbonate. The results show that the procedure depends chiefly on the temperature and on the quantity and fineness of the carbonate used. The method of mixing, the mechanical stirring of the mixture, the concentration of the acid in the solution, and the temperature of the mixture during the reaction also influenced the composition of the final product.

The determination of phosphorus pentoxid after citrate digestion, O. C. SMITH (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1127, 1128).—A method of digestion in which a clear solution (the acid treatment) is easily obtained in an hour or less is described in detail by the author, at the Oklahoma Experiment Station.

On the composition and solubility of acid calcium carbonate, A. CAVAZZI (*Gaz. Chim. Ital.*, 46 (1916), II, No. 2, pp. 122-135).—Experimental data show that by the action of carbon dioxid on an aqueous solution of calcium oxid or on neutral calcium carbonate the bicarbonate,  $\text{Ca}(\text{HCO}_3)_2$ , is formed.

The greatest quantity of calcium carbonate soluble (after prolonged agitation of not less than 10 hours) in 1 liter of water at  $0^\circ$ , saturated with carbon dioxid and maintained so at atmospheric pressure, was 1.56 gm., corresponding to 2.5272 gm. of the bicarbonate. Under analogous conditions at  $15^\circ$  C. 1 liter dissolved 1.1752 gm. calcium carbonate, equivalent to 1.9038 gm. of the bicarbonate.

By passing a rapid current of carbon dioxid through lime water saturated at  $15^\circ$ , the first turbidity formed after about one minute soon clears, and then a supersaturated solution of acid carbonate containing 2.29 gm.  $\text{CaCO}_3$ , equivalent to 3.71 gm. of the bicarbonate per liter, is formed.

The determination of water in plant substances, A. N. LEBEDĀNTSEV and G. I. ZALYGIN (*Zhur. Opytn. Agron. (Jour. Agr. Expt.)*, 17 (1916), No. 3, pp. 181-230).—In the determination of moisture in plant materials by heating to  $100^\circ$  C. in a current of air the authors observed a loss of carbon dioxid and certain other volatile organic substances. A loss of material through oxidation or hydration was thus indicated. Lowering the temperature of heating (from  $80$  to  $60^\circ$ ), diminishing the pressure, or replacing the air with carbon dioxid did not perceptibly influence the loss of volatile matter other than moisture. The most important factor in the amount of loss was found to be the time of heating.

Drying in a desiccator with sulphuric acid or phosphorus pentoxid at normal temperature also caused a loss, the amount depending on the duration of the desiccation. An equilibrium, however, was reached in from four to seven months, so that the actual loss could perhaps be considered negligible.

The unreliability of the methods for the determination of moisture in plant materials commonly used and the necessity of specifying some standards when analytical data are submitted are indicated.

A method for the quantitative determination of free and combined galactose, A. W. VAN DER HAAR (*Chem. Weekbl.*, 13 (1916), No. 44, pp. 1204-1213, fig. 1).—The following procedure for the determination of free galactose, which depends on its oxidation to mucic acid with nitric acid, is described:

A suitable sample (from 50 to 100 mg.) is treated in a beaker with 60 cc. of nitric acid (specific gravity 1.15) and heated on the water bath with occasional shaking until the material in the beaker weighs less than 20 gm. After cooling, water is added until the contents weigh exactly 20 gm. Five hundred mg. pure mucic acid is added and the whole set aside for 48 hours at  $15^\circ$  C., during which time the contents are occasionally agitated. The precipitated

mucic acid is then filtered through asbestos in a Gooch crucible, washed with nitric acid and water, dried, and weighed. From the weight of the material in the crucible the weight of the added mucic acid is subtracted, and the amount of galactose in the original sample is calculated.

For determining galactose in glucosids, a moisture-free sample of from 0.25 to 1 gm. is hydrolyzed with about 25 cc. of from 2 to 5 per cent sulphuric acid. After the hydrolysis is complete the material is allowed to stand for 24 hours, filtered, washed with water, dried, and weighed. The filtrate and washings are treated with dilute alkali until only slightly acid, and then concentrated on the water bath. After sufficient concentration the liquid is made alkaline and 30 cc. of the liquid oxidized with 30 cc. nitric acid (50 per cent). The procedure is then carried out as described above for the determination of free galactose. A curve and tables for converting milligrams of mucic acid to milligrams of galactose up to 1,000 mg. galactose are submitted.

Some analytical data submitted indicate the accuracy of the procedure.

A thermostat or constant-temperature cabinet for the flour-testing laboratory, C. H. BAILEY (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1142-1144, figs. 5).—The construction of a constant-temperature cabinet, used by the author at the Minnesota Experiment Station in baking and fermentation tests, is described. The thermo-element is so arranged that the cabinet can be used to cover a considerable range in temperature. The apparatus can be constructed at a nominal cost.

Investigation and determination of hydrocyanic acid in string beans (haricots), L. GUIGNARD (*Ann. Falsif.*, 9 (1916), No. 94-95, pp. 301-305, figs. 2).—The preparation of a simple test paper for the detection of hydrocyanic acid in beans is described. The solution used contains 1 gm. picric acid in 100 cc. distilled water to which, after complete solution, 10 gm. crystallized potassium carbonate is added. The test is performed by hydrolyzing the pulverized sample in a suitable flask and suspending the paper in the neck of the container. The production of an orange-red color (after sufficient time is allowed for hydrolysis) indicates the presence of a cyanogenetic glucosid.

For the quantitative determination of hydrocyanic acid in imported beans the silver nitrate titration method with the distilled acid is used. This procedure is deemed to yield sufficiently accurate results.

The microscopic character of the bean (*Phaseolus vulgaris*) is also described.

Separation and identification of food-coloring substances, W. E. MATTHEWSON (*U. S. Dept. Agr. Bul.* 448 (1917), pp. 56).—This bulletin describes and discusses a scheme of analysis of dyes which embraces about 130 chemical individuals. The method of separation is based mainly on the use of immiscible solvents.

The general topics considered are reagents used in color analysis, preliminary treatment of food products, separation and purification of coloring substances, and identification of coloring substances. Tabulated data relative to the extraction of coloring substances from aqueous solutions by immiscible solvents, behavior of dry colors or of dyed fibers with reagents, behavior of colors when treated with reducing agents followed by oxidizing agents, classification of colors according to the reactions obtained by the bromin test, behavior of colors when treated with sodium nitrite and with cyanid solution, and the numbers by which dyes are designated in different published tables.

A modification of Price's method for the separation of the seven permitted coal tar dyes to include tartrazin, C. ESTES (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1123, 1124).—A slight modification of Price's method (*E. S. R.*, 25, p. 502) for determining the permissible coal tar dyes, including

the recently admitted tartrazin, is described. A scheme for the separation of the dyes is included.

The determination of butter fat in margarins, G. JORGENSEN (*Ann. Falsif.*, 9 (1916), No. 94-95, pp. 262-270).—On account of the large amount of caproic and caprylic acids in palm and coconut oil the author considers the Reichert-Meissl number unreliable as an index of the amount of butter fat in margarins. The following procedure, in which the water-insoluble silver capronate and caprylate are precipitated as earlier suggested by Kirschner (E. S. R., 16, p. 1050) and Jøensen (E. S. R., 17, p. 697), is described:

To the neutral liquid from the Reichert-Meissl determination 30 cc. of tenth-normal silver nitrate is added. The mixture is then made up to 150 cc., thoroughly agitated, set aside for one hour, and filtered through a folded filter. To 100 cc. of the filtered liquid 20 cc. tenth-normal sodium chlorid is added, and the excess sodium chlorid then titrated with standard silver nitrate, using potassium chromate as indicator. The number of cubic centimeters of silver nitrate used in the titration multiplied by 1.5 gives the amount of insoluble silver salts (*A*), corresponding to the soluble volatile acids. Designating the Reichert-Meissl number as *B*, the silver index is then equal to *B-A*.

Having the silver index and either the Polenske number or the total volatile acids, the percentage of butter fat in the sample is easily calculated by formulas which are submitted and described.

The method is deemed to yield results sufficiently accurate for practical work. A table giving the percentages of butter fat equivalent to the silver indexes obtained, together with the amounts of total volatile acids and Polenske numbers, is included.

A boiling method for the determination of water-soluble arsenic in lead arsenate, G. P. GRAY and A. W. CHRISTIE (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1109-1113).—The authors, at the California Experiment Station, propose the following procedure:

Five-tenths gm. of the dry powder is placed in a 500 cc. Erlenmeyer flask, and after the addition of 200 cc. of distilled water boiled briskly for 10 minutes. If the liquid is cloudy or the material does not settle readily, it should be further digested on the steam bath for an hour or two. The material is filtered, washed with a small quantity of hot water, and the filtrate collected in a 500 cc. Erlenmeyer flask. One gm. potassium iodid and 4 cc. of concentrated sulphuric acid are added and the volume of the liquid reduced to 40 cc. by boiling. The liquid is then diluted to 200 cc., and the free iodine remaining titrated with approximately twentieth-normal sodium thiosulphate. The solution is nearly neutralized with concentrated sodium hydroxid, using methyl orange. Sodium bicarbonate is added to alkalinity and then to excess. The arsenic is titrated with a twentieth-normal iodine solution, starch paste being used as indicator.

The procedure outlined is considered to be shorter than any recommended heretofore, only three to four hours being required for an analysis. It yields accurate results, and its use is inexpensive.

The results obtained by the new procedure are higher than those obtained by the provisional method of the Association of Official Agricultural Chemists, but are deemed to be more nearly correct.

The methods in use at present are briefly reviewed and discussed.

An oxalate-iodid process for Paris green analysis, C. A. PETERS and L. E. FIELDING (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1114, 1115).—A method for the analysis of Paris green, in which the copper is precipitated as oxalate, the combined oxalic acid titrated with permanganate, and the arsenic oxidized in the filtrate by iodine, is described in detail from the Massachusetts

Agricultural College. The method is claimed to yield accurate results and, except for the fact that the copper oxalate must set overnight, is rapid.

The analysis, purification, and some chemical properties of agar agar, C. F. FELLERS (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1128-1133).—The author, at the New Jersey Experiment Stations, discusses and reviews the literature on the sources, preparation, and composition of agar.

The results of the analysis of 16 samples of agar obtained from widely different sources show a remarkable uniformity. Considerably more nitrogen, however, was found in the samples than is usually considered to be present. A percentage ash constituent analysis of three samples is also submitted. A high ash or silica content is considered to be indicative of an inferior product.

A method of preparing a purified agar is described in detail. It consists essentially of washing the agar shreds in a solution of dilute acetic acid, washing out the acid, and precipitating while hot a 5 per cent solution of the agar by means of a large volume of alcohol or acetone. The greater part of the nitrogenous matter is removed by this method, and it is, therefore, recommended for the preparation of material to be used in refined bacteriological work, especially where a medium containing a minimum of nutrients is desired.

"Solutions of agar will solidify at all concentrations of HCl and NaOH between 4.5 per cent HCl and 5 per cent NaOH. Heating at one atmosphere pressure for 15 minutes in an autoclave narrows the range of solidification to from 2 per cent acid to 4.5 per cent alkali. Peptone increases the jellifying power of agar. KCl appears to decrease it slightly." The action of some other chemicals on agar is also noted.

Analytical methods used in sugar chemistry, E. SAILLARD (*Monit. Sci.*, 5. ser., 6 (1916), II, Nos. 897, pp. 193-203; 898, pp. 224-228).—This article describes in detail and discusses methods for the determination of the density of sugar beets, sugar in beets by warm aqueous digestion, sugar by Clerget's inversion method, and invert sugar in the presence of saccharose.

The solubility of calcium sulphite in water and in sugar solution, T. VAN DER LINDEN (*Meded. Proefstat. Java-Suikerindus.*, 6 (1916), No. 10, pp. 307-322).—Tabulated solubility data submitted show that calcium sulphite is only slightly soluble in water and 15 per cent saccharose solution, but is more soluble in the latter than in the former. The solubility in either case varies inversely with the temperature. An excess of lime markedly diminishes the solubility in either solvent.

Data are also submitted on the solubility of calcium sulphite in 15 per cent saccharose plus 1.5 per cent glucose. They do not, however, differ markedly from the solubility figures in the pure saccharose solution.

The practical significance of such solubility data in sugar manufacture is indicated.

Sweet wines of high alcohol content without fortification, W. V. CRUICK, E. M. BROWN, and F. FLOSSFEDER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 12, pp. 1124-1126).—In small-scale fermentations wines of over 18 per cent alcohol were made by the fermentation of grape must with wine yeast and the addition of grape sirup during fermentation. In one of these wines 19.9 per cent alcohol was obtained. The percentages of alcohol thus obtained are considerably higher than the maximum obtained by "straight" fermentation with the same yeast, and the higher yields are, therefore, considered to be undoubtedly due to the addition of the sirup.

Experiments made to determine the character of the invigorating compound of the sirup showed that it was not the sugar. The substance causing the increased activity of the yeast was not determined.

Partly dried grapes, used instead of the sirups, yielded the same results.

The wine made by the new method, if not filtered and carefully handled, was spoiled by the growth of "tourne" bacteria. When properly handled and kept in well-filled containers it kept well and developed an agreeable "sherry" flavor.

The preparation and conservation of fruit juices in the United States, A. TRUELLE (*Vie Agr. et Rurale*, 6 (1916), No. 24, pp. 427-432).—This article discusses general and special methods for the preparation and conservation of fruit juices, as devised and recommended by the U. S. Department of Agriculture (E. S. R., 33, p. 316).

The canning of fruits and vegetables, J. P. ZAVALLA (*New York: John Wiley & Sons*, 1916, pp. XII+214, pl. 1, figs. 68).—This volume discusses the processes, and data relative thereto, of factory fruit and vegetable canning, especially as practiced in California, micro-organisms and spoilage; and the making of sanitary cans. An appendix containing the Pure Foods Act of California, standards of purity, and the Food Sanitation Act, together with a rather complete table of weights and measures, is included.

The fruit-pulp industry, H. BLIN (*Vie Agr. et Rurale*, 6 (1916), No. 35, pp. 149-154, figs. 6).—This article discusses in detail the conservation of fruit by stoning and pulping. The economic importance of conservation by this method is indicated.

Honey vinegar, C. E. BARTHOLOMEW (*Iowa Yearbook Agr.*, 16 (1915), pp. 558-563, figs. 3).—This article discusses the preparation of vinegar from surplus honey, especially the strong honeys which bring a low price on the market. A simple apparatus, easily assembled, for use in converting the alcohol into vinegar, and its manipulation, are described.

Meat preservation on the farm, J. C. MARSHALL (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 10, pp. 596-601).—This article briefly describes methods for the preservation of meat by salting or pickling, sterilization by heat, and preservation by drying.

## METEOROLOGY.

Daytime and nighttime precipitation and their economic significance, J. B. KINCER (*U. S. Mo. Weather Rev.*, 44 (1916), No. 11, pp. 628-633, figs. 10).—Charts and diagrams showing in a general way the variations in diurnal distribution of rainfall for different sections of the country during the period from April to September, inclusive, are given and discussed. These show wide variations in the distribution of rainfall between day and night in different parts of the United States. The outstanding facts are the concentration of daytime rainfall in the Southeastern States and of night rainfall in the central plains States. It is shown that for portions of the Southeastern States only about 25 per cent of the total rain falls at night, while in the central plains district from 60 to 65 per cent or more occurs at night. There is a progressive decrease of the daytime rainfall in the Southeastern States toward the northward and westward. There is likewise a regular and progressive decrease in all directions of the night rainfall of the central plains States.

"The dominance of daytime rains in the Southeast and along the immediate Gulf coast is undoubtedly due to atmospheric convection during the warmer portions of the day, a characteristic of tropical and semitropical rainfall conditions, but just why there should be so well defined an area and so pronounced a type of night rainfall in the central plains region, with a progressive diminution in all directions, is not readily apparent." These are shown to be facts of great economic importance from the standpoint of farming. "In the Southeastern States, where the summer rainfall is usually abundant, the question of diurnal distribution so far as its bearing on the development of vegetation is concerned is not of so great importance." On the other hand, in the central

plains region where the rainfall is limited it is of great importance that the rains occur largely during the night, when they will do the maximum amount of good with the least interference with farm work, especially the harvesting and thrashing of wheat, which is the principal crop of the region.

**Slope and valley air temperatures**, W. R. BLAIR (*Reclam. Rec. [U. S.]*, 8 (1917), No. 1, pp. 40, 41; *U. S. Mo. Weather Rev.*, 44 (1916), No. 12, pp. 677-679).—From a study of the results of three or four years' observations of mountain and valley temperatures in the vicinity of Mount Weather, Va., and by means of captive balloons at Lone Pine and Mount Whitney, Cal., the author concludes that "a little observation on the slopes of a given valley at the time of injurious frosts in the late and in the early autumn should serve to determine with sufficient exactness the height on the slopes above which, for some distance at least, the greatest freedom from such frosts will be experienced. The easiest and most direct way of making these observations is to expose thermographs at different altitudes on the slopes. The balloon is not needed because the upper surface of the cold-air mass in the valley is nearly level, possibly a few meters lower over the middle than at the sides of the valley. This upper surface has been found at 100 to 300 meters above the valley floor at different times of the night and in different localities."

**Types of anticyclones of the United States and their average movements**, E. H. BOWIE and R. H. WEIGHTMAN (*U. S. Mo. Weather Rev.*, *Sup. 4* (1917), pp. 25, pls. 73, figs. 7).—This paper is largely statistical, including, however, brief descriptions of the types of anticyclones which prevail in the United States, their courses, and the resulting weather and temperature conditions. No attempt is made to deal at length with theories concerning their origin, etc., further than to give "a statement of published views concerning the forces that originate, maintain, and propel anticyclones across the United States at a rate of speed that is little less than that of cyclones."

**Graphic method of representing and comparing drought intensities**, T. T. MUNGER (*U. S. Mo. Weather Rev.*, 44 (1916), No. 11, pp. 642, 643, fig. 1).—The construction and use of diagrams consisting of a series of right-angle triangles whose height and base are both proportional to the duration of the drought is described.

**Frequency curves of climatic phenomena**, H. R. TOLLEY (*U. S. Mo. Weather Rev.*, 44 (1916), No. 11, pp. 634-642, figs. 4).—The construction and use of such curves are discussed.

**Monthly Weather Review** (*U. S. Mo. Weather Rev.*, 44 (1916), Nos. 11, pp. 611-669, pls. 9, figs. 17; 12, pp. 671-712, pls. 13, figs. 4).—In addition to weather forecasts, river and flood observations, and seismological reports for November and December, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during November and December, 1916; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 11.—The Duration and Intensity of Twilight (illus.), by H. H. Kimball; Von Bezold's Description of Twilight; Mairan's Description of Anti-twilight; Explanations of the Western Purple Light and the Eastern Afterglow (Nachglühen), by A. Heim; Twilight Phenomena in Arizona, September to December, 1916, by A. E. Douglass; Twilight Colors at Mount Wilson, Cal., August-September, 1916, by W. P. Hoge; Solar Halo of September 28, 1916, at Miami, Fla. (illus.), by R. W. Gray; Metric System for Aeronautics; Measurement of Horizontal and Vertical Movement in the Atmosphere, by M. Tenani; Daytime and Nighttime Precipitation and Their Economic Significance (illus.), by J. B.

Kincer (see p. 717); Frequency Curves of Climatic Phenomena (illus.), by H. R. Tolley (see p. 718); Graphic Method of Representing and Comparing Drought Intensities (illus.), by T. T. Munger (see p. 718); Relation Between Strength of the Trade Winds of the North Atlantic and Temperature in Europe, by P. H. Gallé; Monthly Distribution of Mean Cloudiness Over France, by G. Bigourdan; Path of Sound Rays in Air Under Influence of Temperature, by V. Kommerell; and Six Years of Snowfall Measurements in the Carson, Walker, and Truckee Watersheds, by H. F. Alciatore.

No. 12.—Current Evaporation Observations by the Weather Bureau (illus.), by B. C. Kadel and C. Abbe, jr.; Slope and Valley Air Temperatures, by W. R. Blair (see p. 718); Low Pressure at Paris, November 18, 1916, by [C.] A. Angot; Thunder and Hail in the Paris Region, by [C.] A. Angot; The Kinetic Theory of Evaporation, by A. March; Temperature of the Ocean Below the 500-Fathom Line on the West Coast of America, by A. H. Clark; Surface Currents of Jupiter During 1915–1916, by S. Bolton; William Marriott, 1848–1916; Hurricanes of 1916 and Notes on Hurricanes of 1912–1915 (illus.), by R. H. Weightman; The Alabama Earthquake of October 18, 1916 (illus.), by R. H. Finch; Notes Relating to the Earthquake of October 18, 1916, in North-Central Alabama, by O. B. Hopkins; and Earthquakes Felt in the United States During 1916 (illus.), by W. J. Humphreys.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), Nos. 11, pp. 224, pls. 2, figs. 4; 12, pp. 226, pls. 2, figs. 5*).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for November and December, 1916.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTBANDER and W. P. SAUNDERS (*Massachusetts Sta. Met. Buls., 337–338 (1917), pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1917, are presented. The data are briefly discussed in general notes on the weather of each month.

[Meteorological observations], D. A. SEELEY (*Ann. Rpt. Sec. Bd. Agr. Mich., 55 (1916), pp. 229–240*).—Daily and monthly summaries of temperature (maximum, minimum, and mean), precipitation, cloudiness and sunshine, and monthly summaries of pressure (maximum, minimum, and mean), wind movement, and miscellaneous phenomena (frost, hail, thunderstorms, fog, auroras, and halos) at East Lansing, Mich., are given for the year ended June 30, 1916.

## SOILS—FERTILIZERS.

Measurement of the inactive, or unfree, moisture in the soil by means of the dilatometer method, G. J. BOUYOUKOS (*U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 6, pp. 195–217, fig. 1*).—This paper, prepared at the Michigan Experiment Station, deals with the dilatometer method as a means of showing the amount of water which becomes inactive in soils, as indicated by the amount that fails to freeze. "The principle of the dilatometer method is based upon the fact that water expands upon freezing. . . ."

"The dilatometer consists of three parts: (1) a bulb, (2) a thermometer, and (3) a measuring stem. The method of procedure consists of mixing soil and water in certain definite proportions, placing this moist soil in the bulb, and then filling the latter with ligroin. The bulb with its contents is then placed in a cooling mixture and allowed to supercool. After the desired supercooling is attained the bulb is moved gently in the cooling mixture until solidification commences, which is indicated by the rise of the ligroin in the stem. The

bulb is allowed to remain in the ice mixture with frequent movement until equilibrium is reached. The total rise of the ligroin in the stem is taken to represent the total quantity of water that freezes in the soil.

"It was found that not all of the water added to soils freezes. Some of it fails to freeze, and the quantity that fails to freeze is different in the various classes of soil. Under the empirical conditions of 25 gm. of air-dry soil mixed with 5 cc. of water, supercooled to 3° C. in a temperature of -4°, the quantity that fails to freeze varies from 2 per cent in quartz sand to 80 per cent in clay, of the 5 cc. of water added. It increases, therefore, from the simple and noncolloidal types to the complex and colloidal types of soil.

"In the case of colloidal soils the amount of water that fails to freeze decreases with the increase in supercooling, but in the case of noncolloidal soils it remains the same. By increasing the degree of moisture content, the amount of water that fails to freeze is decreased in the colloidal soils, but remains practically the same in the noncolloidal soils. At the low-moisture content, successive freezings diminish the quantity of the unfrozen water in the case of the colloidal soils, but not in the noncolloidal soils.

"The percentage of water content that fails to freeze in all soils under the empirical conditions [stated] corresponds remarkably closely to the moisture content known as the wilting coefficient, to the percentage of moisture at which solidification can not be started, to the thermal critical moisture content, etc. . . .

"The dilatometer method appears to be of considerable value in showing (1) that soils cause water to become unfree, as indicated by its refusal to freeze; (2) in measuring quantitatively the amount of water thus becoming unfree; (3) in determining, under certain empirical conditions, the wilting coefficient of soils; and (4) in classifying, under certain empirical conditions, the water in the soil into free, capillary, physically adsorbed, and chemically combined."

The soil solution, how it is obtained, its composition and use in mechanical analysis by sedimentation, J. P. VAN ZYL (*Jour. Landw.*, 64 (1916), No. 3, pp. 201-275).—Experiments with a tenacious clay soil on methods of obtaining the soil solution, and its composition and use in mechanical analysis, are reported.

It is concluded that methods hitherto used for obtaining soil solution, especially of heavy soil types, are either not permissible or are impracticable. The pressing out of soil (Auspressen) was found to be a good method for obtaining relatively large amounts of soil solution, especially from naturally very damp soil. The concentration of the soil solution was found to vary considerably not only for different soils but for different samples of soil from the same field. The variations in different soils were due for the most part to fertilization and climatic factors. The percentage composition of the soil solution in a heavy clay soil, on the other hand, remained approximately the same with different fertilization, which is attributed to the strong absorptive power of the soil.

Mechanical analysis with distilled water was found to be the best process for determining the absolute mechanical composition of the soil. The sedimentation process with soil solution was entirely different from that with distilled water. The influence of fertilization and time of year was marked, but the final results were similar to those obtained with distilled water.

It is concluded that the use of the soil solution will give a close indication of the momentary structure of cultivated soil.

Methods of mechanical study of soils, D. J. HISSINK (*Arch. Suikerindus. Nederland. Indië*, 24 (1916), No. 31, pp. 1204-1217).—Several methods of mechanical analysis of soils are discussed.

Reconnaissance soil survey of the San Francisco Bay region, California, L. C. HOLMES and J. W. NELSON (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 112, pls. 4, fig. 1, map 1*).—This survey, made in cooperation with the California Experiment Station, deals with the soils of an area of 2,517,120 acres in western California. "Topographically the area embraces a series of elongated valleys, separated by high hills or mountains, all extending in a general northwest-southeast direction. The valleys are somewhat irregular in outline and range in extent from a few square miles to about 200 square miles. They are usually well drained and consist of nearly level to very gently sloping surfaces with occasional minor stream bottoms."

"The soils of the valleys are principally recent alluvial soils. . . . Those of the hills and mountains are mainly residual and vary with the character of the underlying rocks. Much of the high mountainous area is too rough and broken for agriculture."

Forty-three soil types are mapped, of which the Altamont loam and clay loam and the Altamont, Mariposa, and Sites loams and clay loams cover 20.9 and 20.1 per cent of the area, respectively.

Soil survey of Grant County, Indiana, L. A. HURST, W. I. WATKINS, W. E. THARP, E. HERTENSTEIN, and P. MIDDLETON (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 36, fig. 1, map 1*).—This survey, made in cooperation with the Indiana Department of Geology, deals with the soils of an area of 263,680 acres in northeast central Indiana, which consists of a level to undulating plain broken only along the streams. "Artificial drainage has been installed extensively in the more poorly drained sections of the county."

In addition to muck and peat, nine soil types of six series are mapped, of which the Clyde silty clay loam, Crosby silt loam, Miami silty clay loam, and Miami silt loam cover 34, 20.3, 18.5, and 14.5 per cent of the area, respectively.

Soil survey of Starke County, Indiana, E. J. GRIMES, W. BARRETT, and T. M. BUSHNELL (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 42, fig. 1, map 1*).—This survey, made in cooperation with the Indiana Department of Geology, deals with the soils of an area of 197,120 acres in northwestern Indiana, the topography of which is very flat except for scattered dune-like ridges and irregular areas of sand. "The county lies almost entirely within the Kankakee plain. . . . Practically all the flat lands throughout the county originally were poorly drained. . . . A large total area is yet unclaimed."

Including muck, 10 soil types of 6 series are mapped of which the Plainfield fine sand, Clyde fine sand, Clyde fine sandy loam, and muck cover 31, 17.4, 17.1, and 16.7 per cent of the area, respectively.

Soil survey of Sioux County, Iowa, E. H. SMIES and W. C. BEAN (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 37, fig. 1, map 1*).—This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 489,600 acres in northwestern Iowa, the topography of which varies from undulating to sharply rolling. The surface is that of a broad loessial plain. Drainage is well established. The soils are grouped as loessial, glacial, terrace, and first bottom soils.

Excluding river wash and rough broken land, 9 soil types of 6 series are mapped, of which the Marshall silt loam covers 80.8 per cent of the area.

Soil survey of Ripley County, Missouri, F. Z. HURTON and H. KRUSEKOFF (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 36, fig. 1, map 1*).—This survey, made in cooperation with the Missouri Experiment Station, deals with the soils of an area of 399,360 acres in southeastern Missouri, lying in the Ozark region.

The topography of the uplands varies from level to very hilly. "In general, the western part of the county, west of the Current River, is the more broken, and large areas are too rough and rocky to cultivate. The southeastern corner of the county is in the Mississippi lowland region. The western part of the county is thoroughly drained by the Current River and its tributaries, and the eastern and northern parts by the Little Black River and its tributaries. The drainage of the Mississippi bottoms is poorly established, there being numerous sloughs and abandoned stream channels."

The soils of the county are mainly of residual and alluvial origin, with a small area of loessial origin. Including rough stony land, 17 soil types of 9 series are mapped, of which the Clarksville gravelly loam, stony loam, and silt loam and Decatur gravelly loam cover 20.3, 19.8, 18.3, and 10.8 per cent of the area, respectively.

**Soil survey of Lamoure County, North Dakota.** A. C. ANDERSON, F. Z. HUTTON, T. M. BUSHNELL, M. THOMAS, and M. E. STEBBINS (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 53, fig. 1, map 1*).—This survey, made in cooperation with the North Dakota Experiment Station and the Agricultural and Geological Survey and issued January 30, 1917, deals with the soils of an area of 729,600 acres in southeastern North Dakota.

The eastern and central parts are mostly undulating prairie, and the western part is gently rolling to hilly. "Surface drainage is not well established, but is in most places sufficient where assisted by percolation into the subsoil. . . . The soils of the county fall into four general groups—glacial, glacial-lake and river-terrace, river flood-plains, and eolian soils." Including rough broken land, 25 soil types of 10 series are mapped, of which the Barnes silt loam, the Barnes loam, and the Williams loam cover 51.9, 15.3, and 11.9 per cent of the area, respectively.

**Soil survey of Cambria County, Pennsylvania.** B. B. DERRICK, A. L. PATRICK, and D. C. WIMER (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 32, fig. 1, map 1*).—This survey, made in cooperation with the Pennsylvania State College and Experiment Station, deals with the soils of an area of 445,440 acres in southwest central Pennsylvania lying mainly in the Allegheny Plateau. The topography is uneven to hilly and even mountainous in places. All parts of the county are said to be reached by drainage ways.

The upland soils of the county are of residual origin and the rest of alluvial origin. In addition to rough stony land, 10 soil types of 5 series are mapped, of which the Dekalb gravelly loam, stony loam, and silt loam cover 41.7, 20.6, and 14.1 per cent of the area, respectively.

**A soil survey of the proposed Palouse Irrigation Project.** H. F. HOLTZ (*Washington Sta. Bul., 133 (1916), pp. 3-14, pls. 6*).—This survey deals with the general characteristics and agricultural value of an area of 103,000 acres in southern Franklin County, Wash. The topography is rolling. The survey was divided into seven areas, and mechanical and chemical analyses and determinations of the water-holding capacity were made of representative soil samples from each area.

**Analyses of one hundred West Virginia soils.** F. E. BEAR and R. M. SALTER (*West Virginia Sta. Bul. 161 (1916), pp. 36, fig. 1*).—This bulletin gives a preliminary statement regarding the most prominent soil series of West Virginia, together with the analyses of 100 representative soil samples chosen from certain sections of the State. The latter are taken to indicate that many of the soils analyzed are seriously deficient in phosphorus, nitrogen, organic matter, and lime, while most of them are fairly well supplied with potash.

It was found that 50 per cent of the soils analyzed contained less than 1,000 lbs. of phosphorus per acre to a depth of 6 2/3 in., over 40 per cent contained

less than 2,500 lbs. of nitrogen, and 90 per cent showed a lime requirement averaging over 1 ton of limestone per acre. Eighty per cent of the soils contained more than 20,000 lbs. of potassium per acre to plow depth.

Reconnaissance soil survey of northeastern Wisconsin, A. R. WHITSON, W. J. GEIB, C. THOMPSON, C. B. POST, A. L. BUSER, L. R. SCHOENMANN, and A. E. TAYLOR (*Wis. Geol. and Nat. Hist. Survey Bul. 47 (1916), Soil Ser. 12, pp. 87, pls. 11, figs. 3*).—This survey, made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture, deals with the soils of an area of 3,902,720 acres in northeastern Wisconsin, including Forest, Florence, Marinette, Oconto, Langlade, and Shawano counties. The surface features are characteristic of a glaciated region and the topography varies from level to rolling.

The soils are of glacial origin. Including peat, muck, and rock outcrop, 27 soil types of 11 series are mapped, of which the Kennan silt loam and fine sandy loam cover 22.9 and 10.9 per cent of the area, respectively, and peat 9.8 per cent.

Reconnaissance soil survey of north part of north-central Wisconsin, A. R. WHITSON, W. J. GEIB, T. J. DUNNEWALD, C. B. POST, W. C. BOARDMAN, A. R. ALBERT, A. E. TAYLOR, L. R. SCHOENMANN, and C. THOMPSON (*Wis. Geol. and Nat. Hist. Survey Bul. 50 (1916), Soil Ser. 15, pp. 80, pls. 11, figs. 3*).—This survey, made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture, deals with the soils of an area of 2,707,200 acres in north-central Wisconsin, including Vilas, Oneida, Price, and Iron counties, five townships of Ashland County, and six townships of Rusk County. The surface features are characteristic of a glacial region and the topography varies from level to rolling and hilly and broken.

The soils of the area range in texture from sands of low agricultural value to loams and silt loams. Twenty-eight soil types of nine series are mapped, of which those of the Kennan series are the most extensive.

Soil survey of Columbia County, Wisconsin, A. R. WHITSON, W. J. GEIB, G. W. CONREY, and A. E. TAYLOR (*Wis. Geol. and Nat. Hist. Survey Bul. 49 (1916), Soil Ser. 14, pp. 84, pls. 5, figs. 3*).—This survey has been noted from the Field Operations of the Bureau of Soils of the U. S. Department of Agriculture for 1911 (E. S. R., 31, p. 513).

Soil survey of Jefferson County, Wisconsin, A. R. WHITSON, W. J. GEIB, O. J. NOER, and A. H. MEYER (*Wis. Geol. and Nat. Hist. Survey Bul. 48 (1916), Soil Ser. 13, pp. 78, pls. 4, figs. 3*).—This survey has been noted from the Field Operations of the Bureau of Soils of the U. S. Department of Agriculture for 1912 (E. S. R., 34, p. 322).

Notes on soils analyzed, B. C. ASTON (*Jour. Agr. [New Zeal.], 13 (1916), No. 1, pp. 36-41*).—Chemical analyses of 44 samples of New Zealand soils are reported and discussed.

Soils and crops of Nova Scotia (*Ann. Rpt. Sec. Agr. Nova Scotia, 1915, pt. 3, pp. 206, figs. 40*).—This compilation includes the following special articles bearing on soils: Geological Formations and the Soils of Nova Scotia, Humus, the Most Important Element in a Fertile Soil, The Conservation of Soil Moisture, Farm Yard Manure, and Commercial Fertilizers, by M. Cumming; The Chemistry of Nova Scotia Soils in Relation to the Geological Formations, Chemical and Physical Characters of the Soils of Nova Scotia, and Lime in Relation to Agriculture, by L. C. Harlow; and Underdrainage, by B. H. Landells.

Terracing and drainage of hill soils by the "Kotak" system, G. F. J. BLEIJ (*Terrassering en Drainering op Berggronden volgens het "Kotak" systeem. Surabaya, Java: Nederland.-Ind. Landb. Syndicaat, 1916, pp. 9*).—This is a paper presented at the General Dutch Indian Soil Congress, October, 1916.

Terracing and drainage to prevent erosion of Java hill soils used for the cultivation of tea and coffee are discussed, and the so-called "Kotak" system of terracing practiced is described. In this system small rectangular terraces are employed instead of long terraces with ditches. For coffee a terrace 12 ft. square, with one tree in the middle, is usually constructed, while for tea a terrace 8 ft. square, with four plants, is used. An open drain is placed at the foot of the terrace.

The importance of soil ventilation on the alluvium, A. HOWARD (*Agr. Jour. India, Indian Sci. Cong. No., 1916, pp. 46-52*).—The importance of soil aeration in preventing the yellowing of peach trees, in increasing and hastening the effect of green manuring, and in aiding the maturing of crops is discussed.

Notes on the presence of nitrates in orchard soils, J. H. GOURLEY and V. D. SHUNK (*New Hampshire Sta. Tech. Bul. 11 (1916), pp. 3-31, figs. 9*).—Experiments on the effect of sod, tillage, and lining on the presence of nitrates in light orchard soil with very sandy subsoil are reported.

It was found that "the formation of nitrates is greatly reduced in a sod orchard and from a fertility standpoint is the first limiting factor." Stirring the soil readily increased the rate of nitrification and under a good system of tillage nitrates were usually present in excess of the needs of the trees. Lime also consistently increased nitrification. Moisture was not the limiting factor in the sod plats.

See also a previous note (E. S. R., 33, p. 44).

Some effects of oxygen and carbon dioxid on nitrification and ammonification in soils, J. K. PLUMMER (*New York Cornell Sta. Bul. 384 (1916), pp. 305-330, figs. 5*).—Experiments with Dunkirk clay loam soil on the influence of oxygen and carbon dioxid on ammonification and nitrification are reported.

It was found that vigorous nitrification takes place in sealed flasks as long as there is a supply of oxygen. Of the soil gases studied, oxygen was found to be the limiting constituent. "There is an optimum mixture of this gas (one containing from 35 to 60 per cent of oxygen) for nitrification." From the losses of oxygen from the gas mixtures, it is considered certain that there are other forms of oxidation than that caused by the nitrate bacteria.

A large quantity of carbon dioxid was produced when lime was used, amounting in some instances to nearly 20 per cent. The greatest production of this gas accompanied the point of maximum nitrification. Ammonium sulphate, when applied to the soil without the addition of lime, produced only slight increases in nitrification even after incubation for a period of 28 days. "The small quantity of carbon dioxid formed under such conditions would tend to indicate that ammonium sulphate, when applied to this soil alone, depresses the action of the carbon-dioxid-producing bacteria as well. Taking the results as a whole it can not be said that carbon dioxid has any material effect on nitrification so long as oxygen is present in the atmosphere. It is of little consequence whether the oxygen is diluted with the inert gas nitrogen or with carbon dioxid. When the supply of oxygen becomes limited and anaerobic conditions are produced, denitrification sets in and this continues until practically all the nitrates are destroyed. In no case with these experiments was the combined oxygen liberated in the elementary form during the processes of denitrification."

The results with the distillation method for the determination of ammonia showed that there is no optimum content of oxygen for the production of this compound. The results of all mixtures, except the very high concentrations of oxygen, were practically the same. It seemed to make little difference whether the soil readily increased the rate of nitrification and under a good system of dioxid. Under purely anaerobic conditions, caused by an atmosphere of pure

carbon dioxide, there was somewhat less ammonia produced than when oxygen was present at the beginning. Ammonia was formed in rather large quantities under such conditions. Nitrate determinations showed that nitrates are produced in ammonification tests even though the organic content is high and the period of incubation is short.

A list of 27 references to literature bearing on the subject is appended.

The cause of the disappearance of coumarin, vanillin, pyridin, and quinolin in the soil, W. J. ROBBINS (*Science, n. ser., 44 (1916), No. 1147, pp. 894, 895*).—It was found that when soil in pots was treated with coumarin, vanillin, pyridin, and quinolin separately at a concentration of 1,000 parts per million, the numbers of micro-organisms increased enormously after three months and after, in some cases, an initial decrease in numbers. Additions of the substances to sterile soils and to sterile soils inoculated with nonsterile soil showed that after two months' incubation the growth of wheat plants from sterile seed was not affected in the inoculated soils, but the toxic properties of the compounds were still evident in the sterile soil. These results are taken to indicate that the disappearance of the compounds was due chiefly to biological causes. In this connection three species of bacteria were isolated, one of which uses pyridin as a source of nitrogen, and one vanillin and one coumarin as sources of carbon.

The formation of soda in the soil, E. V. BOBKOV (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 355-365, pl. 1; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 2, pp. 115-125*).—Artificial zeolite washed with a solution of sodium chlorid yielded small but measurable quantities of soda, and the quantity of soda increased with the length of time of the reaction and with an increase of the amount of zeolite. If an excess of sodium salt was added the process of the formation of soda was depressed, but was restored when the washing was repeated.

Loss of fertilizers by leaching, S. E. COLLISON and S. S. WALKER (*Florida Sta. Bul. 132 (1916), pp. 20, figs. 5*).—Five years' experiments on the loss of fertility constituents in the drainage water of fertilized and unfertilized sandy soils in four large steel tanks previously described (*E. S. R., 25, p. 117*) are reported.

The authors conclude that under Florida conditions and with soil similar to that used in this experiment "newly cleared land when exposed to heavy rainfall soon loses much of its fertility through leaching. The fertility of the soil may be maintained by growing legumes and applying fertilizers. Much of the loss may be prevented by growing crops. The greatest loss of fertility from unfertilized soils occurs with the nitrogen, which leaches through in considerable quantities. Nitrification of the soil organic matter, thus changing the nitrogen to a form readily lost by leaching, proceeds rapidly in cultivated soils under Florida conditions.

"Phosphoric acid and potash are lost in small quantities from the unfertilized soil, since they are present largely in insoluble forms. Lime is lost in considerable quantity, thus bringing about an acid condition in the soil.

"When cultivated soils are fertilized with a complete fertilizer, the element lost in largest amounts by leaching is nitrogen. Nitrate of soda leaches more rapidly and in larger amounts than sulphate of ammonia or dried blood. Nitrate of soda should be used in small amounts at frequent intervals and usually as a top-dressing.

"Distribution of rainfall influences to a considerable extent the amounts of the fertilizing constituents which leach through. Soils similar to that used in this work have the capacity for fixing large quantities of phosphoric acid ap-

plied in the form of acid phosphate. Such soils have the capacity for fixing considerable potash, but this power is soon exhausted, and afterwards relatively large amounts of potash are lost through leaching."

[Use of manures in Germany], T. H. MIDDLETON (In *The Recent Development of German Agriculture*. London: *Bd. Agr. and Fisheries*, 1916, pp. 36, 37).—It is stated that "the chief immediate cause of the increased productivity of German soil is the increase in the use of artificial manures." Between 1890 and 1910 the total consumption of artificial fertilizers in Germany is stated to have risen from 1,600,000 to 6,000,000 metric tons. There was a tenfold increase in the use of potash and a threefold increase in the use of basic slag.

"The chief factor in developing the use of artificial manures in Germany was unquestionably a well-organized system of technical education. Investigation at the research stations established the precise uses of these manures; trustworthy advice was supplied by institutions, by peripatetic instructors, by technical leaflets, and by agricultural newspapers," and the farmer, even the backward peasant, brought his method into line with the instruction so given.

It is pointed out that Germany has the advantage not only of great deposits of potash salt but vast tracts of light soils specially benefited by potash manures, and hence very successful results have been secured from the intelligent use of such manures.

Some effects of soluble humus on the growth of plants, W. B. BOTTOMLEY (*Assoc. Franç. Avanc. Sci., Compt. Rend.*, 43 (1914), pp. 969, 970).—This is a summary of a number of experiments made by the author with bacterized peat.

A vegetation experiment on the availability of nitrogenous fertilizers in an arid soil, C. B. LIPMAN and W. F. GERICKE (*Soil Sci.*, 2 (1916), No. 6, pp. 575-581).—Vegetation experiments with barley on an arid sandy soil are reported which showed "the low-grade organic nitrogenous fertilizers and sulphate of ammonia to be far more available than dried blood. This confirms the values as to relative availabilities of these fertilizers obtained by laboratory nitrification method. Nitrates, and especially nitrate of calcium, are far less available in the soil than are the other fertilizers with the exception of dried blood, which is about equal to nitrate of soda but superior to nitrate of calcium.

"These data furnish further evidence in support of the proposal to adopt the nitrification method in some form for the determination of the relative availabilities of fertilizer and soil nitrogen and for determining the needs of a soil for available nitrogen."

A list of references to literature on the subject is given.

Ammonifiability versus nitrifiability as a test for the relative availability of nitrogenous fertilizers, C. B. LIPMAN and P. S. BURGESS (*Soil Sci.*, 3 (1917), No. 1, pp. 63-75).—Ammonification and nitrification experiments with 22 soils, principally arid, and tested with dried blood, high-grade tankage, steamed bone meal, cottonseed meal, and fish guano, are reported. "The ammonifiability data gave the fertilizers in question the reverse position as to availability from those given them by the nitrifiability data."

It is concluded that "the ammonifiability data of fertilizer nitrogen in soils are not useful indicators of the nitrifiability data on the same fertilizers in the same soils. . . . The nitrifiability of a given form of nitrogen should be the most reliable laboratory criterion which we can employ. The laboratory results are now being confirmed by vegetation experiments. Hence there appears to be no reason against adopting nitrifiability as the criterion of availability of nitrogenous fertilizers, for purposes of arid soil conditions at least."

Eight references to literature bearing on the subject are appended.

Technological-chemical research on superphosphates, U. PRATOLONGO (*Ann. Chim. Appl. [Rome]*, 6 (1916), No. 3-4, pp. 59-112, figs. 4; *abs. in Jour. Soc.*

*Chem. Indus.*, 35 (1916), No. 20, pp. 1073, 1074).—A number of samples of superphosphate were examined chemically and with a petrographic microscope, and experiments were made on the conditions of equilibrium of the system, lime, phosphoric acid, and water at 75 and 100° C., and on the influence of various factors on the physical properties of superphosphate.

Contrary to the generally accepted view, the calcium sulphate present in superphosphate prepared from mineral phosphates usually existed mainly or entirely as anhydrate. Only in rare instances was it present chiefly or solely as the dihydrate. In bone superphosphate, on the other hand, the dihydrate was present more frequently. Monocalcium and dicalcium phosphates occurred usually only in the hydrate form, but the anhydrous salts were also sometimes present.

The physical properties of superphosphate are considered to depend chiefly on the amount of the liquid phase which is always present. The liquid phase is defined as the sum of the free water and the free phosphoric acid. Analyses of numerous commercial samples of superphosphate indicated that in general the best products in regard to dryness and friability are those in which the liquid phase is less than 15 per cent. Products containing from 15 to 18 per cent of liquid phase were still dry and friable, those containing 18 to 25 per cent were slightly moist and caked when compressed, while those containing more than 25 per cent of liquid phase were moist and caked readily.

A discussion of the technical preparation of superphosphate is also included.

The preparation of superphosphate from phosphorites, N. P. KOBLIKOV (*Iz Rezult. Veget. Qpytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst.*, 10 (1914), pp. 16-22).—A superphosphate containing 16.2 per cent of water-soluble phosphoric acid was prepared from Perm phosphorite and one containing nearly 12 per cent was prepared from Saratov phosphorite.

Causes that influence the solubility of slowly soluble phosphates in citric acid, A. AITA (*Ann. Chim. Appl. [Rome]*, 6 (1916), No. 3-4, pp. 119-131, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 35 (1916), No. 20, p. 1074).—Experiments are reported which showed that the solubility of the phosphoric acid of mineral phosphates in 2 per cent citric acid was diminished in the presence of sodium silicate or magnesium silicate, but increased in the presence of ferrous sulphate or manganese sulphate in proportion to the concentration of the latter. In the presence of ferric sulphate, ferric chlorid, or aluminum sulphate the solubility increased more rapidly than the concentration of the added salts. It is considered probable that the phosphoric acid of basic slag is present as tricalcium phosphate, and that its relatively high solubility in citric acid is due principally to the effect of the aluminum and ferric ions present. From this, it follows that the difference in price between the phosphoric acid of basic slag and of mineral phosphates is not justified, and that the Wagner citric acid test can not be considered satisfactory since it does not take into account the influence of secondary constituents on the solubility of phosphoric acid.

Valuation of water-soluble v. citrate-soluble phosphoric acid, E. J. PRANKE (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 54, 55).—This is a critical review of reports from the New York, New Jersey, and New England state experiment stations in which the author attempts to show that the higher trade valuation for water-soluble phosphoric acid over citrate-soluble phosphoric acid is unwarranted. He points out that "the retail cost of 'available' phosphoric acid in acid phosphate decreases as the proportion of water-soluble to citrate-soluble increases. At present valuations for total phosphoric acid the organic phosphates cost actually more per unit of citrate-soluble than does the available in acid phosphate. Agricultural considerations are ruled out by definition from any connection with trade values, which are only market quotations."

The Garrison and Philipsburg phosphate fields, Montana, J. T. PARDEE (*U. S. Geol. Survey Bul. 640-K (1917), pp. 195-228, pls. 2, figs. 3*).—This is a report of an investigation of two phosphate beds covering the northeastern part of Granite County and a small adjoining part of Powell County in southwestern Montana.

It is stated that "workable deposits of high-grade rock phosphate (containing 60 per cent or more tricalcium phosphate) occur in both the Garrison and Philipsburg fields. That in the Garrison field lies from 6 to 10 miles north of the town of Garrison and is easily accessible, and the portion considered as available to mining contains by estimate 97,000,000 long tons. . . . About one-third of the amount lies above the natural drainage levels, and much of the portion can be very readily extracted by means of adits driven along the phosphate bed."

[Biotite, phonolite, and similar mineral substances as sources of potash for plants], F. V. CHIRIKOV (T. C. TCHIRIKOV) (*Iz Result. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 366-370; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 2, pp. 126-130*).—Experiments are reported which indicate that biotite and muscovite, and rocks containing nepheline and biotite, are very good sources of potash for plants; on the other hand, orthoclase and other forms of feldspar contain potash in a very unavailable form. Ammonium salts which increase the availability of phosphorites do not give like results with the slightly soluble potash minerals. The potash of artificial zeolite, which is very available in solutions containing salts of other bases, becomes almost unavailable if the possibility of exchange of the potash of the zeolite and other bases is removed. The effect produced by various potash minerals on plants is proportional to their power of exchanging potash with other bases.

Blast-furnace slag as a source of bases for acid soils, J. W. AMES (*Mo. Bul. Ohio Sta., 1 (1916), No. 12, pp. 359-362*).—Pot experiments are reported, the results of which are taken to indicate "that furnace slag is not as efficient as limestone or lime. The use of slag as a substitute for either on acid soils is not recommended in any other than an experimental way. To obtain the same effect on acid soils as would result from moderate application of lime or ground limestone, a much larger amount of slag would be required."

The fertilizer value of city waste.—I. The composition of garbage, W. J. O'BRIEN and J. R. LINDEMUTH (*Jour. Indus. and Engin. Chem., 9 (1917), No. 1, pp. 49-54*).—Analyses of 75 samples of garbage taken at regular intervals throughout a year in the District of Columbia showed that there was an unimportant seasonal variation in the moisture content, the maximum falling in July and the minimum in April. "This seems to be a product of a seasonal change both in diet and rainfall. It fails to show that it is of sufficient magnitude seriously to affect the commercial success of a garbage-rendering plant.

"The analysis of 128 samples of garbage taken from 16 sections, of known characteristics, of the city through a range of time of four or five months failed to show any marked or consistent variations. The conclusion is indicated that the kitchen refuse from the establishments of the various classes of inhabitants is essentially alike in content of fats and the elements of fertilizer value. This is without regard to relative quantities. Its importance lies in the fact that it tends to refute the prevalent opinion that the garbage of certain cities can not be rendered profitably because of the nature of its inhabitants."

Commercial fertilizers, 1916, C. D. WOODS ET AL. (*Maine Sta. Off. Insp. 80 (1916), pp. 137-196*).—This bulletin contains the results of actual and guaranteed analyses of 1,112 samples of fertilizers and fertilizing materials collected for

inspection in Maine during 1916. It was found that on the whole the fertilizers analyzed were well up to the guaranty.

**Analysis of fertilizers for 1916**, B. E. CURRY and T. O. SMITH (*New Hampshire Sta. Bul. 179 (1916), pp. 10*).—This bulletin contains the results of actual and guaranteed analyses of 140 samples of fertilizers and fertilizing materials collected for inspection in New Hampshire during 1916. It is stated that a little less than half the brands inspected carried 1 per cent of potash.

## AGRICULTURAL BOTANY.

**Experimental studies in the physiology of heredity**, F. F. BLACKMAN ET AL. (*Abs. in Rpt. Brit. Assoc. Adv. Sci., 85 (1915), pp. 233, 234*).—This is the report of a committee of the association, giving a summary of the work being carried on by R. P. Gregory and H. B. Killby, by the latter alone, by Miss Gairdner, and by Edith R. Saunders (*E. S. R., 34, p. 822*).

The studies on the genetics and cytology of the tetraploid races of *Primula sinensis* have been continued, and progress has been made in the recognition and testing of the heterozygous types *AAAA*, *AAaa*, and *Aaaa*. The phenomena of coupling and repulsion have been further studied in both the diploid and tetraploid races.

The work has been continued on beans and vegetable marrows, on wall flowers and *Tropæolum*, and on foxgloves and stocks. In case of the last named, it appears possible to show how an ever-sporting type may be synthesized from a true breeding individual. Further progress has been made in the study of the inheritance of the half-hoary character and in the identification of theoretical types not found in commercial material. Evidences indicate that excessive percentages of doubles quoted by growers are due to unconscious selection and that the actual output of doubles is not in excess of that required by theory.

**The calculation of linkage intensities**, R. A. EMERSON (*Amer. Nat., 50 (1916), No. 595, pp. 411-420, fig. 1*).—Discussing the methods in use for estimating the intensity of linkage, the author presents formulas for use in the approximation of gametic ratios directly from the  $F_2$  data, without the use of coefficients of association and without respect to whether coupling or repulsion is involved. A single formula leading to accurate results in either case is given, together with others developed from this fundamental formula.

**Morphology and evolution of leaves**, O. F. COOK (*Jour. Wash. Acad. Sci., 6 (1916), No. 15, pp. 537-547*).—The author, discussing the primitive function of leaves and the course and results of specialization in the variously related structures, states that leaves of angiosperms show a primary division into a basal sheath and an expanded blade supported thereby, as represented in leaves of palms, grasses, and other plants. The organs usually described as petioles appear to have arisen through the narrowing of the base of the blade or the primitive sheath. The name foot is suggested as appropriate for the specialized portion of the leaf sheath that serves as a petiole, both petiole and foot being represented in several families named. The author considers also as specializations of the primitive sheath element such structures as stipules, bud scales, bracts, ligules, pulvini, and probably even the blade itself.

**Preliminary observations on the nature and distribution of the statolith apparatus in plants**, MISS T. L. PRANKARD (*Abs. in Rpt. Brit. Assoc. Adv. Sci., 85 (1915), p. 722*).—Statoliths, or bodies free to fall within the cell (statocyte) which contains them, are found in various forms in different parts of plants throughout a wide range of classification. These bodies are not universally connected with the presence of starch. Statoliths are often chloroplasts and

for this form the term chlorostatoliths is proposed. Statoliths may be specialized in shape, size, or behavior of the nucleus.

The statolith apparatus consists of the whole system of statocytes occurring in the various tissues of the plant, or else of cells themselves forming a tissue, for which the term statenchyma has been proposed. Modifications and transitional forms occur. The statolith is considered by the author as an intensive mechanism, the simplest form of statocyte being the living cell itself, the highest a cell containing relatively heavy bodies differentiated as to size and mobility. Between these extremes occur may transitional stages.

The influence of gaseous pressure on growth, ETHEL McCLENNAN (*Proc. Roy. Soc. Victoria, n. ser., 28 (1916), No. 2, pp. 245-250*).—Seedlings of *Pisum arvense*, observed while growing in a moist atmosphere at different air pressures, showed retardation usually in one day, the amount of retardation corresponding somewhat to the pressure. The plant accommodates itself to the pressure and the growth rate gradually rises. The mechanical effect of pressure upon turgor appears to be negligible as a factor determining growth. The influence in this connection of an increase in the oxygen dissolved in the tissues has not been determined.

Concerning the transformation of pigments of plastids in (the) living tissues of plants, V. N. LUBIMENKO (LUBIMENKO) (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 9 (1915), No. 10, pp. 933-935*).—This is a preliminary report of the results of investigations which will later be published in detail.

The author states that all the transformations of pigments of plastids in the living tissues of plants are determined by the activities of oxidizing and reducing enzymes of the cell protoplasm, and the accumulation of a given pigment depends on the relation between the energy of oxidizing and reducing reactions in the cell. Particularly, the quantity and accumulation of chlorophyll in plastids in the presence of normal food supply is determined by the intensity of oxidizing reactions in the cell. This also explains the connection between greening and temperature.

Light does not play a direct part in the chemical transformation of leucophyll into chlorophyll, nor is there a direct correlation between the quantity of chlorophyll and the energy of growth. The author emphasizes the presence of a special enzyme in the juices of the green plants provisionally termed by him antioxidase. It paralyzes the oxidizing action of peroxidase on the pigments of plastids and, unlike peroxidase, is highly sensitive to antiseptics. Morphological differentiation of the organisms of the higher green plants, it is said, is accompanied by their physiological differentiation in the sense of different intensity of oxidizing reactions. From the physiological viewpoint, plastids show a considerable independence with regard to the cell protoplasm and may be compared with leucocytes in animal bodies.

Concerning the mechanism of photosynthesis, A. A. RIKHTER (RICHTER) and E. M. KOLLEGORSKAYA (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 9 (1915), No. 5, pp. 457-467*).—A new method for quantitative studies of photosynthesis is described by the authors, in which a specially constructed apparatus and cultures of *Photobacterium italicum* were made use of. They come to the conclusion that plants differing in their ecological relations require the same initial intensity of light for the decomposition of carbon dioxide. It is noted, however, that with those plants which are enabled to concentrate light by means of special anatomical arrangements the intensity of light necessary for the separation of oxygen in photosynthesis may be much lower than with plants lacking such arrangements.

The distribution of reducing sugar in beets, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 33 (1916), No. 7-9, pp. 161-169).—It is stated that the proportion of reducing sugars in beet root is nearly the same in the middle as in the upper and lower portions, and in the yellowed as in the normally colored beets of the same field. However, the proportion varies from time to time and may be small in mature roots.

Studies upon the maturity of grains, I. A. BLAGOVIESHCHEŃSKĪĪ (BLAGOVESČENSKIĪ) (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd)*, 6. ser., 10 (1916), No. 6, pp. 423-434, fig. 1).—This investigation deals with synthetic reactions which take place in maturing seeds and ultimately lead to the formation of certain higher compounds, such as proteins, starch, and cellulose. The horse bean (*Vicia faba minor*) was selected for these studies for the reason that it contains approximately equal amounts of proteins and starch and very little fat. The analyses of the contents were made at several different stages of maturity, and the results are given in detail.

The ash content showed an increase in absolute quantity and a decrease in percentage. The same phenomenon was observed with the general amount of nitrogen. Starch, on the contrary, steadily increased both absolutely and relatively as the process of ripening advanced. The same changes occurred in the amount of cellulose.

It was noted also that similar synthetic reactions take place in the seeds during their ripening under artificial conditions—that is, after they are separated from the mother plant.

[Report of the research assistant in plant physiology], R. P. HIBBARD (*Michigan Sta. Rpt. 1916*, pp. 274-276).—In connection with his studies on the absorption of solutes, with special reference to balanced solutions, the author found in water cultures with wheat and peas that a solution containing only potassium phosphate, calcium nitrate, and magnesium sulphate produced as good results the first five weeks of growth as where additional salts were used. The effect on photosynthesis in corn and cucumber plants of a nutrient solution lacking a single element has also been studied, and it is claimed that the amount of photosynthate in leaves can not always be taken as an indication of vigor.

On the interpretation of the results of water culture experiments, W. STILES (*Ann. Bot. [London]*, 30 (1916), No. 119, pp. 427-436).—This is mainly a discussion of the differences between the results and conclusions arrived at by the author in a previous contribution (*E. S. R.*, 33, p. 223) and those offered by Miss Brenchley (*E. S. R.*, 35, p. 436).

The effect of vanillin and salicylic aldehyde in culture solution and the action of chemicals in altering their influence, J. J. SKINNER (*Plant World*, 19 (1916), No. 12, pp. 371-378, figs. 3).—In the experiments reported, the effect of vanillin on the growth of cowpeas and on the absorption of nutrients from the solution and the action of manganese in altering the effect of vanillin and salicylic aldehyde were studied.

In the first series of experiments, vanillin was shown to be detrimental to the growth of cowpeas, and the absorption of salts was also less from the solutions containing vanillin than from the controls without that compound. Considering all the cultures, the phosphate absorption was reduced 21 per cent, the nitrate 10, and the potash 33.

In studying the effect of manganese on vanillin and salicylic aldehyde, wheat seedlings were employed. It was found that the harmful action of these substances was partially overcome by manganese, even when this was present in small amount.

Antagonism between manganese and iron in the growth of wheat, W. E. TOTTINGHAM and A. J. BECK (*Plant World*, 19 (1916), No. 12, pp. 359-370, figs.

2).—The authors report on a study of the effects of equimolecular proportions of manganous and ferric chlorids on the growth of two varieties of wheat plants in water cultures. Knop's solution was used as the culture medium, and two concentrations were employed of each salt,  $\frac{M}{1,000}$  and  $\frac{M}{100,000}$ . The study was limited to the antagonistic relations between manganese and iron in the belief that the chlorotic effects due to manganese might indicate interference with the rôle of iron in the production of chlorophyll.

Attention is particularly called to the prevalence of the toxic effect of manganese over iron at the low plane of supply. It is shown that for the growth of roots even the low plane of manganous chlorid is toxic. When the higher concentrations were used, ferric chlorid exerted stronger effects than manganous chlorid upon the growth and color of the varieties of wheat.

Electromotive phenomena in plants, A. D. WALLER ET AL. (*Rpt. Brit. Assoc. Adv. Sci.*, 85 (1915), pp. 218-226, figs. 2).—This is a committee report of studies by A. D. and A. M. Waller, regarding investigations of the electrical measurement of the vitality of vegetable tissues. In pursuance of experiments described in a previous report (E. S. R., 32, p. 522), the authors have endeavored to estimate the relative vitality of the plumules and radicles of seedlings by measuring the voltage of the blaze currents excited by single induction shocks, employing for this purpose seedlings of *Hordeum vulgare*. Tests were applied to the separated plumule and the radicle respectively on the fourth and on the sixth day of germination. The results are given in tabular detail.

Alterations of temperature are said to give rise to considerable alterations in the magnitude of blaze currents and of electrical conductivity, so these observations were made within the range of 18 to 20° C. The seeds must be soaked for a certain time before they will give off their full blaze current. The electrical response of a plumule of *H. vulgare* is of considerably higher voltage than that of a radicle. In consequence of excitation, the electrical resistance of a plant is diminished. The diminution is attributed to the chemical dissociation which has given to the blaze current. It is greater after strong than after weak excitation and the increased conductivity appears to be in relation with the magnitude of the previous blaze current.

The work during 1915 was intended to ascertain whether the blaze currents can be used as a practical test of the germination value of seeds. The result of such tests to peas are considered to show that an average blaze current of 0.03 or 0.04 volt indicate a high class seed, of which about 97 per cent would germinate, individual peas out of the series tested ranging in response from 0.01 or 0.02 to 0.07 or 0.09 volt. The electrical test is much quicker than the germination test and is thought likely to become a practical means to ascertain quickly the germination value of seeds in the market. The authors are still engaged in making tests on different varieties of seeds.

The effect of electrical stimulus on the permeability of plant cells, R. KOKETSU (*Bot. Mag. [Tokyo]*, 30 (1916), No. 355, pp. 264-266).—Experiments are briefly noted in which it is claimed to have been shown that, by the application of electrical stimulus, the plasma membranes of epidermal cells are rendered more readily permeable to dissolved substances.

The influence of defoliation on the development of sugar beet, H. PELLET (*Bul. Assoc. Chim. Sucri. et Distill.*, 33 (1916), No. 7-9, pp. 150-161, figs. 2).—It is considered as proved, by the tests here described, that defoliation of beet influences the weight and sugar content of the root. This result is more marked as removal of the leaves is more frequent and more complete, the production of the new leaves thus drawing upon the materials in the root.

The effect of insecticides on flowering plants, A. F. SHREIBER (SCHREIBER) (*Trudy Būro Prikl. Bot. (Bul. Appl. Bot.)*, 9 (1916), No. 4, pp. 175, 176).—The spraying of *Calendula officinalis* with a decoction of aloes and *Veratrum album* for the control of the cabbage moth (*Mamestra brassicæ*) is said to have shown no unfavorable effect on the flowers or the development of seeds.

Snow cracks on trees as an indication of the amount of bending, T. MAEKAWA (*Bot. Mag. [Tokyo]*, 30 (1916), No. 353, pp. 179–184, pl. 1).—The author has recorded his observations on the effects of wind in cracking the ice and snow on the base, body, and branches of different species of trees during the progress of a violent snowstorm in Sapporo, Japan, February 24, 1915. The meteorological data for the period are also detailed in connection therewith.

The ecological significance of soil aeration, W. A. CANNON and E. E. FREE (*Science*, n. ser., 45 (1917), No. 1156, pp. 178–180).—The authors report independent laboratory investigations on the relation of plant roots to the composition of the soil atmosphere and especially to a deficiency of oxygen or excess of carbon dioxide in this atmosphere.

Basing their conclusions upon these experiments, the authors consider it probable that soil aeration must be added as a factor of no less importance in plant growth than temperature and water. In many semiarid regions shallow basins without outlet occur, the central portions of which are flooded during the rainy seasons but are dry for most of the year. It is characteristic of these regions that they are void of plant life during most of the year and that no perennials are to be found in the lowest places, even where there is no excess accumulation of salts in the soil. It is suggested that the probable reason for the absence of plant life in such regions may be directly traceable to insufficient soil aeration at a time when the soil is suitably moist and at a temperature suitable for the growth of plants. About these playas are frequently observed well-marked bands or zones of plant life and it is thought that these represent the unlike response of the roots of the plants comprising the different zones to the atmosphere of the soil.

Distribution of the cacti with especial reference to the rôle played by the root response to soil temperature and soil moisture, W. A. CANNON (*Amer. Nat.*, 50 (1916), No. 595, pp. 435–442).—This is an examination of the evidence obtainable as drawn from various sources, one discussed at some length in this connection being the report of the Australian Prickly Pear Traveling Commission (E. S. R., 33, p. 134).

While soil moisture is an indispensable condition for the presence of cacti, temperature appears to be a very important limiting factor. Shallow placing of the roots subjects the plant to both high and low extremes of temperature and gives it access to the moisture resulting from very slight rainfall. An effective growth takes place only at relatively high soil temperatures when a certain but highly variable amount of moisture is present in the soil. The determination of the superficial position of the root system of cacti is thought possibly, from studies not yet published, to result from the plant's response to the oxygen supply of the soil.

Osmotic pressure in roots and leaves of plants with respect to the moisture contents of their habitats, V. S. IL'IN (ILJIN), P. S. NAZAROVA (NASAROVA), and M. K. OSTROVSKAĀ (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd)*, 6. ser., 9 (1915), No. 8, pp. 749–768).—The authors have constantly observed a very close connection between the degree of osmotic pressure and the amount of moisture placed at the disposal of plant cells. They find that the higher the moisture content of the soil, the lower is the osmotic pressure in the roots. It is lower in meadow plants than in prairie (steppe) plants and still

lower in swamp plants. Osmotic pressure in the leaves is frequently higher than that in the roots and is not always correlated with the latter, but is determined by conditions of humidity.

**Transpiration and assimilation in steppe plants, V. S. IL'IN (ILJIN)** (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd)*, 6. ser., 9 (1915), No. 4, pp. 346-367, fig. 1).—The rates of transpiration and assimilation and their relationship in various prairie plants were studied and determined. Absolute quantities obtained at a given time and for a given amount of material were reduced to one hour per 1 gm. of dry weight and the amount of water which plants transpire for each cubic centimeter of decomposed carbon dioxide was calculated.

The results of 15 experiments were identical. They show that the plants adapted to a dry habitat are capable of a better usage of moisture and lose less water per unit of decomposed carbon dioxide than is the case with mesophytes. The mesophytes are uneconomical in the use of water and are compelled to close the stomata in order to lessen transpiration, thus considerably reducing or even completely checking assimilation, while in xerophytes under the same conditions these processes are going on at a normal rate. Mesophytes, however, under their normal moisture conditions, quite often lose less water than do xerophytes in their natural habitat, although the rate of transpiration of the former would rise to a high degree if they were transferred to the conditions normal for xerophytes.

With regard to water requirements and the ability to withstand drought, the author puts the steppe plants studied in the following order: *Stipa capillata*, *Centaurea sibirica*, *Phlomis pungens*, *Caragana frutescens*, *Centaurea orientalis*, and, possibly, *Amygdalus nana*, the first one being the most, and the last one the least resistant.

**Teratological notes.—I, Abnormal seedlings, A. D. HARDY** (*Proc. Roy. Soc. Victoria, n. ser.*, 28 (1916), No. 2, pp. 240-244, pl. 1).—In this and papers to follow it is intended to record occurrences of interest to specialists in vegetable teratology which the author has observed within the past few years. The present paper discusses polycotyly, polyphyly, bifurcation of axis, cohesion of cotyledons, and other abnormalities. In future papers his purpose is to deal with heterotaxy and morphological deviations in foliage, etc., in older plants, particularly with reference to indigenous flora.

**Identity of cohoba, the narcotic snuff of ancient Haiti, W. E. SAFFORD** (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 15, pp. 547-562, figs. 3).—The results are given of a study of cohoba, a narcotic snuff which the aborigines of Haiti inhaled through a bifurcated tube for its intoxicating or hypnotic effects. The snuff hitherto thought by many writers to be a form of tobacco was in reality prepared from the seeds of the tree *Piptadenia peregrina*, resembling mimosa, which is widespread in South America and elsewhere. The intoxicating principle is at present unknown.

**A fungus producing hydrocyanic acid and benzoic aldehyde, H. GUYOT** (*[Trav.] Inst. Bot. Univ. Genève*, 9. ser., No. 3 (1915), pp. 22-24, fig. 1).—A fungus, supposed to be a new species of *Mucor*, has been studied on different substrata. It produces considerable amounts of benzoic aldehyde and of hydrocyanic acid.

## FIELD CROPS.

**Report of division of farm crops, V. M. SHOESMITH and F. A. SPRAGG** (*Michigan Sta. Rpt.*, 1916, pp. 285-292).—Rotation and fertilizer experiments that have been in progress for the 5-year period 1911-1915 are briefly reported.

The investment of \$5.73 in a complete fertilizer applied to wheat gave a crop increase for the rotation having a net profit of \$13.51. The use of acid phosphate and muriate of potash showed a net profit of \$12.79. Acid phosphate alone has given slightly better results than nitrate of soda and acid phosphate, and also than raw rock phosphate.

Large increases in yield of both corn and wheat from the use of manure are noted, together with the high values placed on the manure on the basis of these increases. The net value of yard manure per ton was estimated to be \$2.68 and that of stall manure \$3.15. By the addition of 200 lbs. of acid phosphate per acre the net value of stall manure was increased to \$6.26 per ton after paying the cost of the fertilizer.

Results of top-dressing and plowing under manure for wheat indicated a value of manure for top-dressing of \$5.54 per ton and when turned under of \$6.15 per ton.

Further data are given showing the average yields and the average annual values of various crops grown continuously or in rotation for the purpose of determining the cost of producing them.

A general review of crop improvement work given by F. A. Spragg, includes notes on selection work with wheat, beans, peas, and alfalfa.

Investigations in inheritance of shape and size in beans are noted. The data obtained to date indicate a Mendellan segregation of one pair of characters in size inheritance, large size being dominant.

Individual alfalfa plants were observed setting new leaves on old stems that had been defoliated by leaf spot, the plants attaining maturity and setting seed. The progeny of the best of these plants is being propagated.

The extension to nursery work of methods involving the coefficient of yield previously described (E. S. R., 34, p. 735), is noted.

[Field crop experiments], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. [etc.] Antigua, 1914-15, pp. 5-20*).—Variety tests with sweet potatoes, cassavas, eddoes, tannias, yams, corn, and cotton are reported, as well as tillage experiments, distance-of-planting tests, fertilizer experiments, and plant breeding experiments with corn. The plant breeding experiments consist of selection work on local corn, acclimatization of imported varieties, and the propagation of new varieties. In cotton selection work a hybrid has been developed from a cross of Sea Island with St. Eustatius which gives much promise for the future. Brief notes are given on onions, soy beans, garden beans, and peas.

Report on field experiments, 1914, R. M. WILSON and J. H. SMITH (*Essex Ed. Committee, Rpt. Field Expts., 1914, pp. 3-34*).—This is a report of co-operative field experiments conducted in Essex for 1914, including variety tests with winter wheat, barley, oats, potatoes, mangels, corn, and peas, several experiments noted below, and some minor experiments with sorghum, alfalfas, and western-wolths grass.

It was found that a change of seed had considerable influence on the potato crop and that seed secured from Scotland gave the best results. Fertilizer tests with mangels indicated that nitrate of soda and acid phosphate increase the yields. Basic slag proved superior to acid phosphate on heavy soils. Marrow-Stem kale and kohlrabi proved superior to the other green crops tested, due to their drought-resistant qualities. Some notes are given on the feeding value of different types of flax, together with a brief discussion of the cultivation and harvesting of the crop. Riga seed grown in Holland is recommended for planting. In fertilizer tests with pasture land applications of sodium nitrate gave better results than acid phosphate.

Fall-sown grains in Maryland and Virginia, T. R. STANTON (*U. S. Dept. Agr., Farmers' Bul. 786 (1917), pp. 23, figs. 5*).—This discusses methods and

practices relative to the growing of fall-sown grains in Delaware, Maryland, Virginia, and West Virginia, with recommendations as to the best varieties of the various grains to grow, based on tests made with winter wheat (bearded and beardless), winter spelt and emmer, winter rye, winter oats, and winter barley.

Seed-flax production, C. H. CLARK (*U. S. Dept. Agr., Farmers' Bul. 785 (1917), pp. 19, figs. 9*).—This discusses the methods and practices of flax-seed production in the United States, emphasizing not only the value of flax on new sod but also its possibilities in the older agricultural districts.

Flax varieties grown in the United States are roughly divided into (1) seed flax, (2) short fiber flax, and (3) textile fiber flax. In tests at 10 stations in the northern Great Plains area west of the Red River valley, where flax wilt is not serious, the seed-flax varieties have given uniformly better results than the short fiber flaxes. North Dakota No. 155, or some selection from it, has usually given the highest yield, while North Dakota Resistant Nos. 52 and 73 and similar strains have also proved excellent varieties.

In subhumid sections farther east, North Dakota Resistant No. 114 and Primost (Minnesota No. 25) have been widely distributed.

Tests with flax in a 6-year rotation of 3 years of alfalfa and 1 year each of corn, flax, and sugar beets in comparison with flax grown continuously have been conducted at the Belle Fourche and Huntley experiment farms (E. S. R., 33, p. 829; 36, p. 132). At Huntley the average yield of flax in the rotation for the first 4-year period was 25.8 bu., the highest yield being 31.3 bu. The average yield of continuously cropped plats was 10.1 bu., and the highest yield 14.5 bu. The yield of the continuously cropped field has increased each year.

Similar results were obtained at the Belle Fourche station. The 1914 flax plat in the 6-year rotation yielded 21.4 bu., while the yield of the continuously cropped plat was 7.5 bu.

A rotation similar to the above in the irrigated rotation series at the Scottsbluff experiment farm has not given as satisfactory results, due largely to unfavorable weather conditions. These tests are being continued.

Change of sex in hemp, F. J. PRITCHARD (*Jour. Heredity, 7 (1916), No. 7, pp. 325-329, fig. 1*).—The differences of opinion regarding the effect of external stimuli upon sex ratios led the author to undertake investigations with hemp in an effort to determine the following: (1) Can sex ratios of dioecious plants be altered by modifying conditions external to their germ cells? (2) Is the alteration thus obtained limited to individuals of one sex? (3) How do results harmonize with the Mendelian conception of sex determination?

The hemp plant was employed because it is almost wholly composed of distinctly unisexual individuals, although monoecious individuals (which were distinctly female in type) also appeared. The plant's physiological equilibrium was disturbed by the removal of flowers and other vegetative parts and by the injection of the following chemical substances into the stem: Calcium nitrate 0.1, zinc sulphate 0.1, dextrose 5, maltose 5, peptone 1, asparagin 0.5, potassium iodid 3 per cent, pyridin  $\frac{n}{25}$ , formic acid  $\frac{n}{16000}$ , acetic acid  $\frac{n}{60}$ ,  $\frac{n}{30}$ , sodium hydrate  $\frac{n}{300}$ ,  $\frac{n}{100}$ ,  $\frac{n}{60}$ . Two hundred and sixty-three plants were mutilated by the removal of flowers, flower buds, leaves, and portions of the stem. The tops of 20 were bagged and 60 others received injections of the above-named chemicals. The discussion covers the results obtained from two years' experimental work.

Alteration of sex occurred under several different treatments, the removal of parts being the only factor, however, common to all the sex-developing responses.

Of the 163 plants which produce flowers after treatment, 29 developed some flowers of the opposite sex. Four of these plants were males and 25 females.

It is evident that the sex of hemp is alterable by the removal of flowers. Although only a few male plants produced pistils, they constituted from 14 to 21 per cent of the total number of males producing flowers after mutilation, while the females were very responsive to the stimulus of flower removal. In the second year's experiments every female mutilated produced stamens. These results seem to indicate that sex is not wholly a matter of zygotic constitution but that both males and females are potential hermaphrodites, as believed by Darwin and Strasburger.

Rice variety studies, E. VAN DRENT (*Dept. Landb. Suriname Verslag, 1915, pp. 62-66*).—This is a brief account of some rice variety trials, including a study of the plat arrangement employed. Each of the five varieties tested were sown in three parallel plats, the planting distances being 0.5, 1, and 1.5 ft., respectively. Brief notes are given on the cultural characteristics of each variety with special reference to their resistance to wind. No conclusions as to the best distance for planting could be drawn, but the experiments will be continued in 1916 with two varieties, using the same system of plats, and from these it is hoped to obtain definite results.

[Sugar cane] (*Hawaii. Sugar Planters' Sta. Proc., 35 (1915), pp. 20-26, 64-80, 86-113*).—Progress in variety testing at the Waipio substation and in cooperative field tests is reported. Leguminous seeds are being distributed for the production of green manure crops. The most desirable crops for this purpose are san hemp and the Bengal bean. Reports of the committees on cultivation, fertilization, and irrigation on irrigated plantations and on cultivation and fertilization on unirrigated plantations are given, together with a discussion thereof.

Breeding sugar cane (*Jour. Heredity, 7 (1916), No. 9, p. 405*).—This is a brief note on sugar cane breeding in Porto Rico. Hand pollination has been found almost impossible, due to the smallness of the flower, the height at which the inflorescence is produced, and its brittleness. Wind pollination has been accomplished by planting a pollen-sterile variety on the leeward side of a pollen-fertile variety.

Studies in Indian sugar canes.—II, Sugar cane seedlings, including some correlations between morphological characters and sucrose in the juice, C. A. BARBER (*Mem. Dept. Agr. India, Bot. Ser., 8 (1916), No. 3, pp. 103-199, pls. 32, figs. 2*).—This gives a detailed account of studies of sugar-cane seedlings.

In an effort to increase sugar production in India, sugar-cane seedlings have been propagated at Coimbatore in Madras, where the cane flowers profusely. The seedlings obtained are enumerated and described by periods, representing the periods of seed production. Variations in nine morphological characters, viz, vigor and size, general habit of growth, erectness of young shoots, tillering, leaf types, width of leaf, color of leaf, color of cane, and thickness of cane, and in the sucrose percentage in the juice are discussed in detail. A number of correlations between the morphological characters of the seedlings and the richness of their juice have also been studied. These correlations are as follows: Leaf width and sucrose, length of leaf and sucrose, leaf nodule and sucrose, thickness of cane and sucrose, length of cane and sucrose, cane module and sucrose, leaf width and thickness of cane, leaf width and total weight of seedling, leaf width and tillering, and color of cane and sucrose.

Production of sugar in the United States and foreign countries, P. ELLIOTT (*U. S. Dept. Agr. Bul. 473 (1917), pp. 70*).—Statistics are given for the United States and 37 other countries on the production of cane and beet sugar for the period from September 1, 1903, when the Brussels Convention went into effect,

to the close of the sugar year 1912-13, with a comparison of the preceding decade.

The total world production of both beet and cane sugar increased from about 11,000,000 tons in 1893-94 to 20,000,000 tons in 1912-13. The average annual world output for the decade 1904-1913 was 16,419,000 tons, as compared with 11,498,000 tons for the preceding decade. The production of beet sugar for these two periods shows an increase of 34 per cent, while cane-sugar production increased 40 per cent. This latter increase was largely due to improved industrial conditions in Cuba, where alone an increase of 152 per cent was realized. An increase of 85 per cent was realized in Java.

It is estimated that over 12,000,000 acres are harvested annually to produce the world's sugar supply, this acreage being about equally divided between beets and cane. The yield of sugar beets per acre has varied from 1,800 to 3,900 lbs., while cane sugar has varied from 2,000 to 9,000 lbs. Hawaii and Java exceeded all other countries in the production of sugar per acre, amounting to 4.5 to 5 tons for some years in Hawaii. These countries also led in the production of cane, averaging about 40 tons per acre. The United States had the highest production of beet sugar per factory employee, so far as data are available, the output amounting to 59.8 tons annually as compared with 22.97 tons for Hungary, 20.61 for France, 13.95 for Austria, 11.42 for Russia, and 19.09 for cane sugar for Hawaii.

During 1904-1913 78.9 per cent of the world's output of sugar was produced in 11 countries, as follows: British India, 14.5; Germany, 13.6; Cuba, 10.3; Austria-Hungary, Java, and Russia, 8 each; United States and France, 4.7 each; Hawaii, 3; and Belgium and the Netherlands, 1.5 each.

Cuba exceeded all other countries in the exports of sugar for the last decade, while the United States exceeded all other countries in imports. The United States also led all other countries in the consumption of sugar, with an increase of 42.9 per cent over the preceding decade. During the decade 1904-1913 Australia exceeded all other countries in per capita consumption of sugar, amounting to 112.96 lbs.

Statistics for each country are discussed in detail.

**Manuring of swedes with different phosphatic manures; purchase of basic slag** (*Univ. Col. N. Wales, Bangor, Dept. Agr. [Pub.], 6 (1914), pp. 7*).—These experiments were begun in 1913 at eight centers in North Wales to determine whether basic slag should be purchased on the basis of total phosphorus or on the amount of phosphorus soluble in a 2 per cent citric acid solution and the comparative value of basic slag, acid phosphate, and mineral phosphate as a fertilizer for swedes on North Wales soils. The experiments are to be continued further, but the results obtained thus far indicate that basic slag will give as good results as acid phosphate if used in such quantities that the crop receives an equivalent amount of phosphorus soluble in 2 per cent citric acid, and that mineral phosphates, if finely ground, are to be recommended for swedes.

**Manuring of swedes with different phosphatic manures** (*Univ. Col. N. Wales, Bangor, Dept. Agr. [Pub.], 6 (1915), pp. 4*).—A continuation of the experiments noted above indicates that a liberal application of phosphatic fertilizers is essential for the production of swedes, and that basic slag and acid phosphate have produced the highest yields.

**The suppression of characters on crossing, R. H. BIFFEN** (*Jour. Genetics, 5 (1916), No. 4, pp. 225-228*).—This article deals with the study of the association of the mouse-gray color occurring in the glumes of the Rivet wheat (*Triticum turgidum*) and the presence of a quantity of hairs on the glumes. It is offered as a contribution to the information by Bateson and Pellew (E.

S. R., 34, p. 41), in which it is shown that a group of characters introduced by one of the original parents failed to affect the  $F_2$  generation.

The author has found that all gray-chaffed wheats are rough-chaffed, but that all rough-chaffed wheats are not gray. In the  $F_2$  generation in crosses of Rivet wheat with Polish wheat (*T. polonicum*) having white glumes, over 2,000 plants raised from 20 separate  $F_1$  crosses had the identical glume color of Polish wheat. Cases are cited where red-grained varieties, in which the parents bred true to color, when crossed produced white-grained varieties. The suppression of a dominant character in the  $F_2$  generation, from parents showing dominant characters only, is thought to be more frequent in wheats than it appears to be at present. It is suggested that this suppression may be due to the existence of more than one determining factor for the dominant character (in this case, color), and that consequently two factors determining the recessive character may occasionally meet in the zygote, thus completely suppressing the dominant.

Work in connection with Egyptian wheat, G. C. DUDGEON and G. BOLLAND (*Min. Agr. Egypt. Tech. and Sci. Serv. Bul. 7 (1916), pp. 9*).—This bulletin outlines investigations being conducted with native and imported wheat at the Ghezeh School of Agriculture, together with a discussion of the results obtained thus far. The native types are of the Baladi variety. Imported seed from England, America, Russia, Cyprus, Australia, and Sudan, were sown between November 18 and December 1, 1914. These varieties were badly infested with rust and in 1915 only three native varieties and the Muzaffarnagar wheat of India were sown. Of these varieties the White Baladi gave the highest yield.

An experiment was also undertaken to determine the rate of seeding and the comparative value of plowing in and harrowing in the seed. The same variety was used in all tests, and a rate of 6 keleh per feddan (2.5 bu. per acre) harrowed in gave the best results.

A series of experiments to determine the best method of treating seed for the prevention of smut included treatments with copper sulphate solutions varying in strength from 0.5 to 10 per cent and with Cyllin from 1:2,000 to 1:250. The results obtained indicate that all the treatments greatly reduced smut infection, but that the copper sulphate solutions stronger than 2 per cent and all the Cyllin solutions were too strong and reduced germination.

Carman's wheat-rye hybrids, C. E. LEIGHTY (*Jour. Heredity, 7 (1916), No. 9, pp. 420-427, figs. 4*).—This is a comprehensive summary of the work of Elbert S. Carman, a former editor of the *Rural New Yorker*, in his attempts to establish a wheat-rye hybrid. The fact is brought out by the author that many of the supposed hybrids in the *Rural New Yorker* series show no trace of rye characters and that only one variety originated from a real wheat-rye hybrid. This variety, known as No. 6, is an actual descendant from the true wheat-rye hybrid obtained in 1883.

Seed reports, 1914, 1915, J. W. KELLOGG and H. E. GENSLER (*Penn. Dept. Agr. Buls. 258 (1915), pp. 35; 276 (1916), pp. 35, figs. 5*).—A report of the seed inspection for 1914 and 1915 is given. A copy of the seed law, directions for sampling seed, and the standards of purity used in seed testing are included in the report for 1914, while in that for 1915 100 noxious weed seeds found in farm seeds are described and illustrated.

Results of seed tests for 1916, F. W. TAYLOR and F. S. PRINCE (*New Hampshire Sta. Bul. 180 (1916), pp. 18*).—This reports the analysis of 84 samples of seed collected by the station during the year 1916, and other data.

Michigan weeds, W. J. BEAL (*Michigan Sta. Bul. 267, 2. ed. (1915), pp. 181, figs. 248*).—This is a revised edition of a bulletin previously noted (*E. S. R., 27, p. 343*), following the American Code of Nomenclature in the second edition

(1913) of Britton and Brown's Illustrated Flora of the Northeastern United States and Canada as a standard for the botanical names.

Kill garlic and wild onion by oil spraying, A. D. SELBY and D. R. VAN ATTA (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 12, pp. 355-358, figs. 2).—The eradication of *Allium vineale* and *A. canadense* in Hamilton County, Ohio, by the use of fuel oil as a spray is briefly discussed.

Similar work conducted by the Indiana Experiment Station (E. S. R., 31, p. 739) with orchard heating oil is noted.

Eradication of bracken (*Univ. Col. N. Wales, Bangor, Dept. Agr. [Pub.] 5 (1914), pp. 7*).—This publication reports further experiments, conducted on six experimental farms, in the eradication of bracken in pasture lands. The indications are that by the end of the second year the bracken had been nearly exhausted by repeated cuttings, while the grass had been stimulated by the application of lime and manures.

Improvement of hill and peaty pastures; eradication of bracken (*Univ. Col. N. Wales, Bangor, Dept. Agr. [Pub.] 3 (1915), pp. 8*).—Experiments have been laid out at 15 centers for the treatment of poor pastures on peaty or hilly ground with basic slag, ground limestone, rock phosphate, and acid phosphate. The general results to date indicate that basic slag and rock phosphate improve pasture conditions, while lime used alone has had little or no effect.

Experiments with the eradication of bracken have been continued with much the same results as noted above.

## HORTICULTURE.

On the problem of extra root nutrition and treatment of trees, V. LUBIMENKO (LUBIMENKO) (*Zap. Imp. Nikitsk. Sada [Alta]*, No. 6 (1914), pp. 91-181, figs. 6).—Experiments on the introduction of various solutions into the wood of growing trees are reported in detail. The solutions were introduced into the tree through a glass siphon attached to holes bored with an auger 5 mm. (0.2 in.) in diameter and bored to a depth of 1.5 to 2 cm. (0.6 to 0.8 in.).

The author found in part that the successful introduction of solutions into living trees is largely dependent upon exclusion of air from the holes and upon reduced root pressure accompanied by partial desiccation of the wood cells, i. e., reduced sap content. Other conditions being equal, the greater the amount of desiccation the greater the amount of solution absorbed and the wider its distribution throughout the tree. The solution filtering into the partially desiccated wood elements spreads in all directions, both lengthwise and crosswise of the fibers, filtration being more rapid lengthwise of the fibers. In cases where desiccation is severe enough to affect the roots infiltration of solutions may take place through the roots as well as through the trunk.

Of the species experimented with, the pear, apple, and peach are easily subject to desiccation of the wood during the summer period. The plum and the wild cherry tree are not so easily a prey to desiccation, while the ailanthus, Judas tree, cypress, lanuginous oak, Chinese privet, and the white mulberry are least subject to desiccation. Even with the first class of trees it is necessary to undertake these experiments during the hot and dry season when the desiccation of the wood is at its height.

As the quantity of liquid absorbed by the wood by means of infiltration into the elements emptied of sap depends on its degree of desiccation it is impossible to determine beforehand how many openings should be bored into the trunk and what the dimensions should be in order to obtain a uniform impregnation of the wood. The general rule given is that the smaller the

diameter of the tree and the drier its wood the smaller the number of the openings for uniform impregnation.

Although the author arrived at no conclusion as to the practical value of introducing solutions in tree trunks it is believed that the results obtained indicate that the method is worthy of further study, particularly with trees such as the pear and apple, that are subject to drying during the hot summer period.

Some observations upon the relation of humidity to the ripening and storage of fruits, A. D. SHAMEL (*Mo. Bul. Com. Hort. Cal.*, 6 (1917), No. 2, pp. 39-41).—Some data are given on experiments conducted by the author in co-operation with F. F. Chase in a lemon storage and packing house at Corona, Cal., during the 3-year period, 1914-1916.

In an experimental curing of a roomful of lemons with the room maintained for four weeks at about 90° F. and about 90 per cent relative humidity more than 90 per cent of the cut stems of the fruits calloused over perfectly in the same manner that cuttings callous over under favorable conditions. Further experiments showed that the development of the calloused condition depended largely upon the maintenance of a uniform condition of relative humidity. Callous developed more rapidly at a high temperature, such as 95°, than at a low temperature, such as 60°. With the daily humidity fluctuating from 50 per cent to 95 per cent very little development of callous was observed.

With uniformly high relative humidity of about 90 per cent comparatively little loss of weight in the fruits was observed irrespective of the temperature during the storage. The lemons also developed a smoother texture, lighter color, and better commercial appearance than where a condition of low relative humidity, e. g., 70 per cent, was maintained, or where the relative humidity fluctuated considerably during the storage.

On August 4, 1916, a box of hard, ripe Bartlett pears was placed with the lemons in one of the curing rooms, where temperature and humidity records were taken for 30 days. At the same time a similar lot of pears was placed in a family storage room without regard to temperature or humidity. The pears in the family storage room turned yellow and ripened perfectly by August 10, whereas the pears in the lemon room remained hard and green until the end of the experiment on September 3. At the beginning of the experiment these pears were exposed to a temperature as low as 83°. For the most part after this date the temperature was very high, reaching 100° on August 27. The relative humidity was uniformly high, being 96 per cent on August 17 and ranging from 85 to 96 per cent between August 5 and August 21. The humidity was below 80 per cent only nine days out of the period. Sample pears removed from the lemon room from time to time ripened within six or seven days from the date of withdrawal.

In lieu of further observations no definite explanation is offered why the pears were held for 30 days at the high temperatures recorded without ripening or deteriorating. The investigators believe, however, that the condition of high relative humidity was a controlling factor in retarding ripening.

Statistics of fruits in principal countries, H. D. RUDDIMAN (*U. S. Dept. Agr. Bul.* 483 (1917), pp. 40).—A brief statistical survey of production, exports, and imports of fruits for the United States and other important producing, exporting, and consuming countries. The data given are based upon figures taken from official sources, usually from publications of the countries treated.

Minnesota State Fruit-Breeding Farm in 1916, C. HARALSON (*Minn. Hort.*, 45 (1917), No. 2, pp. 49-55, pl. 1, figs. 2).—A brief progress report on breeding work with apples, strawberries, raspberries, grapes, plums, and cherries, with discussion following.

Report on investigations of the botanical laboratory of the Imperial Nikitsky Orchard in 1912 (*Zap. Imp. Nikitsk. Sada [Īalta]*, No. 6 (1914), pp. 183-200, pls. 5).—Experiments in crossbreeding with peaches, apples, pears, and grapes are reported.

Experiments in the production of parthenocarpic apples and pears by preventing pollination were for the most part negative, only one apple and four pears being secured. Experiments in ringing fruit branches resulted in a rapid dying off of the branches and consequent loss of fruit. A study of the influence of seeds of the apple on the development of the pericarp showed a close relation between seeds and pericarp development. The greater the number of seed the greater was their influence on the pericarp.

Apple growing (*Mass. [Bd.] Agr. Bul. 2, 5. ed., rev. (1916)*, pp. 258, pls. 25, figs. 31).—Some of the articles in the previous edition of this bulletin (E. S. R., 30, p. 739) have been superseded by new ones and a number of other new articles relating to apple growing have been added. The subject matter as a whole has been revised where deemed necessary.

The apple in Canada, its cultivation and improvement, W. T. MACOUN (*Canada Expt. Farms Bul. 86 (1916)*, pp. 136, figs. 25).—This bulletin records the results of experimental work with the apple at the Central Experimental Farm and branch farms and stations of Canada, and gives information relative to best methods of propagating apples, varieties recommended, and the planting and care of orchards. The experimental data recorded deal largely with investigations with seedling and cross-bred apples, yields of individual trees of the same varieties, the closely planted Wealthy apple orchard, and other work previously reported on from time to time (E. S. R., 33, p. 236).

Harvesting, packing, and marketing the apple crop, A. F. MASON (*Penn. State Col. Ext. Circ. 50 (1916)*, pp. 44, figs. 34).—A popular treatise on the subject, including illustrated descriptions of various types of grading and sizing machinery.

Sending apples by parcel post, P. THAYER (*Mo. Bul. Ohio Sta., 1 (1916)*, No. 12, pp. 377-382, figs. 6).—An account of the station's experience in marketing apples by parcel post during the past three years. The styles of packages used are illustrated and described and the results of shipping tests for each year are given.

The results in general show that apples when not too ripe and when well packed will carry to almost any distance with little or no injury. For short distances, as within the second postal zone, and for small quantities parcel post is much cheaper than express. For large quantities or greater distances express rates are cheaper. To insure profit packages must be put up in quantities in advance of orders.

The native pears of North Africa, L. TRABUT (*Bul. Sta. Forest. Nord Afrique, 1 (1916)*, No. 4, pp. 115-120, pls. 4, figs. 3).—Observations on the geographic distribution of pears native to North Africa.

Problems and opportunities in the fig industry, J. E. COIT (*Cal. Citrogr., 2 (1917)*, No. 5, pp. 6, 7, figs. 3).—An outline of some of the problems in fig culture under investigation by the California Experiment Station.

Statistics on the production of grapes in 1916 (*Estadística de la Producción Vitícola en el Año 1916. Madrid: Govt., 1917*, pp. 6).—The usual statistical report on the production of grapes and wine in various regions and Provinces of Spain (E. S. R., 35, p. 744) during the year 1916, including comparative data for the five years commencing in 1912.

Tropical pomology.—A new field for horticulturists, W. POPENOE (*Univ. Cal. Jour. Agr., 3 (1916)*, No. 6, pp. 221-228, figs. 2).—Popular suggestions are

given relative to the possibilities of improving various tropical fruits and methods of growing them.

The navel orange of Bahia; with notes on some little-known Brazilian fruits, P. H. DORSETT, A. D. SHAMEL, and W. POPENOE (*U. S. Dept. Agr. Bul. 445 (1917), pp. 35, pls. 24, fig. 1*).—In addition to an account of the origin, history, and culture of the navel orange of Bahia, together with the introduction of the Washington navel orange of Bahia into the United States, notes are given on other citrus fruits and miscellaneous fruits grown at Bahia, citrus fruits and other fruits growing in the region around Rio de Janeiro, and fruits of the highlands and semiarid regions of Minas Geraes and Bahia. Comparative analyses of navel oranges grown at Riverside, Cal., and at Bahia, Brazil, made by H. C. Gore, are included.

The use of commercial fertilizers, J. F. BREAZEALE (*Cal. Citrogr., 2 (1917), No. 5, pp. 4, 5*).—A popular discussion of some of the fundamentals of fertilizer practice, with special reference to citrus groves.

The pomegranate, R. W. HODGSON (*California Sta. Bul. 276 (1917), pp. 163-192, figs. 15*).—An account of the pomegranate with reference to its range of culture in the United States, history, botany, horticultural varieties, climatic requirements, propagation, soils, orchard management, yields, returns, uses, diseases, insect pests, and other troubles.

Planting pecans, budding, grafting, and transplanting pecan trees, J. A. EVANS (*Tex. Agr. Col. Ext. Serv. Bul. B-85 (1917), pp. 32, figs. 8*).—Practical instructions on budding, grafting, planting, and transplanting pecans are given, including information relative to varieties adapted to different sections of the State.

Profitable herb growing and collecting, ADA B. TEETGEN (*London: Country Life, 1916, pp. XI+180, figs. 16*).—A compilation of information gleaned from publications issued by departments of agriculture in different countries concerning the culture, yield, profitable marketing, and kinds of medicinal plants and herbs.

Observations and experiments in poppy culture and the production of opium in the Province of Valladolid, Spain, C. BENAIGES DE AERIS (*Bol. Agr. Téc. y Econ., 9 (1917), No. 97, pp. 55-63*).—Notes on poppy and opium production in general, including experimental results obtained on the Valladolid Farm.

The dahlia, L. K. PEACOCK (*Berlin, N. J.: Peacock Dahlia Farms [1917], 5. ed., pp. 80, pl. 1, figs. 62*).—A practical treatise on the habits, characteristics, cultivation, and history of the dahlia, including also descriptive lists of varieties.

Parks: Their design, equipment, and use, G. BURNAP (*Philadelphia and London: J. B. Lippincott Co., 1916, pp. 328, pl. 1, figs. 167*).—A treatise on the principles of park design, comprising as a whole a guide for town and city officials intrusted with the development and maintenance of parks, a reference work for landscape architects and superintendents in designing parks, and a general work for the enlightenment of the public. The principles of design are here illustrated by photographs of parks in various cities and countries.

The successive chapters discuss park design in city planning, bringing up a park the way it should go, principles of park design, "passing-through" parks, neighborhood parks, recreation parks, playgrounds in parks, effigies and monuments in parks, architecture in parks, decorative use of water, planting design of parks, park administration in relation to planting design, seats in public parks, disposition of flowers in parks, and park utilities.

The food garden, W. F. ROWLES (*London: Headley Bros. [1917], pp. 324, pls. 28, figs. 50*).—A manual on the culture and conservation of fruits and vegetables, with special reference to the home garden and greenhouse.

From garden to pantry, NELLIE R. DE LISSA (*London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. [1916], pp. 110*).—A small practical treatise on the culture, harvesting, and home conservation of vegetables and fruits.

Vegetable growing, J. G. BOYLE (*Philadelphia and New York: Lea & Febiger, 1917, pp. IX+17-350, figs. 154*).—A text-book and treatise on the principles and practice of vegetable growing, with special reference to the home garden.

Report of the bureau of insecticides and fungicides for the year 1915, S. K. JOHNSON ET AL. (*Columbus, Ohio: State, 1916, pp. 37*).—This report contains tabulated analyses of insecticides and fungicides inspected under the Ohio insecticide and fungicide law in 1915, together with short articles relating to inspection work, the text of the Ohio insecticide and fungicide law, and a fruit-growers' spray calendar.

## FORESTRY.

Forest terminology (*Jour. Forestry, 15 (1917), No. 1, pp. 68-101*).—A list of terms in forestry compiled by a committee of the Society of American Foresters, together with a statement of principles guiding the committee in choosing terms. A number of the terms appearing in Bulletin 61 of the Forest Service of the U. S. Department of Agriculture (E. S. R., 17, p. 373) have been ruled out in the present list as either ill chosen or not necessary.

The situation, B. E. FERNOW (*Jour. Forestry, 15 (1917), No. 1, pp. 3-14*).—A review of progress made in forestry in the United States as a policy, science, and art during the past 30 years.

Sixth biennial report of the state forester of the State of California, G. M. HOMANS (*Bien. Rpt. State Forester Cal., 6 (1915-16), pp. 56, figs. 17*).—A report of activities during the biennial period 1915-16, including information relative to forest fire protection work by private, state, and federal agencies; city tree-planting work and legislation for its promotion; data on private eucalyptus plantations; and recommended legislation.

A short paper on Summer Homes on the National Forests, by C. DuBois, is also included.

Biennial report of the forestry commission for the years 1915-16, W. R. BROWN ET AL. (*Bien. Rpt. Forestry Com. N. H., 1915-16, pp. 177, pls. 19*).—A report for the biennial period 1915-16 giving a synopsis of the growth and present status of the state forestry work and reviewing recent progress along the following lines: The forest-fire service; reforestation; operations on the national, state, and municipal forests in New Hampshire; and educational and special projects. The state forest laws and data on the fire-service organization are appended.

Division of forestry and parks, F. B. MOODY (*Bien. Rpt. State Conserv. Com. Wis., 1915-16, pp. 69-138, figs. 23*).—A report of activities for the biennial period 1915-16 relative to forest protection, work on the state parks, forest-planting operations, and assistance rendered to private owners. The text is given of the forest-fire plan for protection of headwaters of the Wisconsin and Chippewa rivers, as developed by the Wisconsin Conservation Commission in cooperation with the Federal Government and others, together with papers by C. L. Harrington on State Forest Nurseries and on the Extent, Value, and Use of Wisconsin Woodlots. It contains the decision of the Supreme Court of Wisconsin restricting land purchases for extending the State Forest Reserve and reviews the forest fire protection work.

Continuous forest production of privately owned timber lands as a solution of the economic difficulties of the lumber industry, B. P. KIRKLAND (*Jour. Forestry, 15 (1917), No. 1, pp. 15-64*).—In this paper the author reviews

existing conditions affecting the lumber industry, with special reference to destructive competition; presents data to justify forestry as a permanent business proposition; and emphasizes the importance of organized control, whether by public or private agencies. Suggestions are given relative to methods of controlling the lumber industry.

**Farm woodlot timber: Its uses and principal markets, G. N. LAMB** (*Purdue Univ. Dept. Agr. Ext. Bul. 51* (1916), pp. 24, figs. 2).—An account of the native commercial species, their uses, specifications, market prices, and important markets for woodlot products. The subject matter is based on a study of Indiana woodlots conducted by the Forest Service of the U. S. Department of Agriculture in cooperation with the Department of Agricultural Extension of Purdue University.

**Trees planted by new machine replace railway snow fences, H. SMITH** (*Engin. News, 77* (1917), No. 11, pp. 432, 433, figs. 4).—Planting plans used in forming windbreaks in place of snow fences along the Minneapolis, St. Paul, and Sault Ste. Marie Railway are given. A tree-planting machine successfully used in this work is illustrated and described.

**The Christmas tree industry, E. SECREST** (*Mo. Bul. Ohio Sta., 1* (1916), No. 12, pp. 371-374, fig. 1).—Popular suggestions are given relative to the planting, care, and marketing of Christmas trees.

**The greenheart of commerce, C. D. MELL** (*Amer. Forestry, 22* (1916), No. 269, pp. 288-291, figs. 6).—A popular account of the greenheart tree (*Nectandra rodiei*), of the Guianas and Venezuela, relative to its distinguishing characteristics, exploitation, mechanical properties, and commercial importance.

**True mahogany, C. D. MELL** (*U. S. Dept. Agr. Bul. 474* (1917), pp. 24, pls. 3, figs. 4).—An account of the true mahogany (*Swietenia* spp.) with reference to its common names, geographical distribution, general characteristics of the wood, characteristics of the wood from different regions, market value, uses and supply, importations to the United States, methods of logging and transportation, botanical characteristics, and minute characters of the wood. The author concludes with a list of cabinet woods from various countries which resemble true mahogany in one or more characters and are frequently marketed as mahogany.

**Contribution to the knowledge of red quebracho, J. B. GALARZA** (*Trab. Inst. Bot. y Farmacol., Buenos Aires, No. 32* (1915), pp. 69, pls. 2, figs. 31).—An account of the red quebracho (*Schinopsis* spp.), with reference to its botany, histology, geographic distribution, exploitation of lumber and tannin extract, physical and chemical properties, commerce, and uses. Data on mechanical tests of the wood are given and the strength values compared with various other Argentine woods. Analytical data are also given showing the tannin content of numerous samples.

A bibliography of cited literature is appended.

**Lumbering in the sugar and yellow pine region of California, S. BERRY** (*U. S. Dept. Agr. Bul. 440* (1917), pp. 99, pls. 14, fig. 1).—The introductory part of this bulletin gives a general account of the region, the forest, types of operations, labor, camps, and factors affecting the cut. Part 2 treats in detail of logging operations, including the preparing of logs for transport, the various stages of transportation, and woods supervision. Part 3 discusses the manufacture of lumber, and part 4 deals with general cost factors, consideration being given to overhead charges, depreciation, and the costs of typical operations.

**An annotated list of the forest trees of the Hawaiian archipelago, V. MACCAUGHEY** (*Bul. Torrey Bot. Club, 44* (1917), No. 3, pp. 145-157).—A check list to the Hawaiian arborescent flora.

British-grown timber and timber trees, A. D. WEBSTER (*London: William Rider & Son, Ltd., 1916, pp. XII+164, pls. 41, fig. 1*).—A concise description of each species, together with notes as to their value for ornamental and economic planting, including an account of the soils suited to their cultivation, the uses to which the timber is applied, the current value of the wood, etc.

### DISEASES OF PLANTS.

[Report of the research assistant in plant pathology], G. H. COONS (*Michigan Sta. Rpt. 1916, pp. 265-274*).—The author describes the various lines of work in progress during the year, particular attention having been paid to the cause and control of a certain limb and twig disease of the apple. The disease in question was found to be due to *Plenodomus fuscomaculans*, and preliminary accounts of some of the phases of the investigation have already been given (*E. S. R.*, 34, p. 647; 35, p. 653) in connection with investigations carried on under the author's direction.

Considerable advance has been made in the study of bean diseases and their control, and while preventive treatment by hot water or chemicals has given little promise for the control of bean anthracnose and blight, it has been found possible by the planting of resistant varieties to escape serious losses. In connection with this investigation, the feasibility of growing beans for seed purposes in western regions where blight does not exist has been demonstrated.

Some notes are given on investigations of potato diseases, particularly a wilt due to *Fusarium*, the efficiency of some forms of sterilization of soil in connection with the growing of celery, and miscellaneous pests of potatoes, grain, and vegetables. Among the vegetable diseases reported upon is a fruit rot of tomato, from which a yellow bacterial organism has been isolated that seems to differ from *Bacterium michiganense*, especially in the fact that no wilting of the stem occurs.

[Plant diseases in Uganda, 1915], R. FYFFE (*Ann. Rpt. Bot., Forestry and Sci. Dept. Uganda, 1915, pp. 5, 6*).—It is stated that Para rubber trees suffered considerably during the year from attacks on the roots by *Fomes semitostus* and *Hymenochaete noxia*. The former is found to propagate itself only by means of mycelium. Both are controlled by trenches isolating affected areas, by sprinkling lime around affected trees, and by exposing the roots to the sun's rays.

A few pods of cacao (*Theobroma cacao*) affected with brown rot (*Phytophthora faberi*) were burnt, this being considered to be the best means for control of the disease.

Costa Rica coffee plants were found to be susceptible to *Hemileia vastatrix* as are any of the other varieties of coffee cultivated in this country. A variety of coffee grown from seed obtained from the Sese Islands appears to be the most resistant yet tried, except perhaps a single old tree of *Coffea liberica* said to be very robust but of slow growth.

Phytopathological work in the Tropics, J. R. JOHNSTON (*Phytopathology, 6 (1916), No. 5, pp. 381-386*).—Attention is called to the necessity of phytopathological studies in the Tropics, and some of the work in progress is briefly described. A plan is outlined for a greater amount of cooperation in investigations and a better coordination of efforts for the control of plant diseases in the American Tropics.

Facultative heteroecism of *Peridermium harknessii* and *Cronartium quercus*, F. D. FROMME (*Phytopathology, 6 (1916), No. 5, pp. 411, 412*).—The author criticizes the conclusion of Meinecke (*E. S. R.*, 36, p. 454) regarding facultative heteroecism in these two rusts and states that the cases cited do not meet the

requirements which would establish this claim. The ability of these rusts to exist in the absence of an alternate host plant is indicated, but this alone does not constitute autœcism nor facultative heterœcism.

**Studies of the genus *Phytophthora*, J. ROSENBAUM** (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 7, pp. 233-276, pls. 7, figs. 13; *Proc. Nat. Acad. Sci.*, 3 (1917), No. 3, pp. 159-163).—Based on cultural and other studies of 11 of the 13 described species of *Phytophthora*, a tentative key is presented for the identification of the species.

**Mechanism of tumor growth in crown gall, E. F. SMITH** (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 5, pp. 165-188, pls. 62).—A detailed account is given of experiments previously reported (*E. S. R.*, 36, p. 46), with suggestions as to what is believed to be the proximate cause of the abnormal cell proliferation in crown gall. The experiments described are considered to have an important bearing not only on the production of crown gall and other tumors in plants but also on the origin of animal tumors.

The author believes that in the local osmotic action (possibly, in some stages, chemical action also) of various substances thrown into cells and diffusing from them in all directions, as the result of the metabolism of a feeble intracellular parasite or symbiont together with the resultant counter movements of water and food supply, there is, in crown gall at least and presumptively also in animal neoplasms, an explanation of tumor growth.

**Intoxicating bread, N. A. NAUMOV** (*Min. Zeml. [Russia], Trudy Būuro Mikol. i Fitopatol., Uchen. Kom.*, No. 12 (1916), pp. 216, pls. 8, fig. 1).—This publication represents a further progress report of work on the disease of grain called "drunk bread" (*E. S. R.*, 35, p. 845).

The author has made extensive studies of this disease, especially the relation of the causal organisms to the hosts, their biology, and possible control measures. It is definitely stated that this trouble of cereals is due to the activities of two species of *Fusarium*, *F. roseum* and *F. subulatum*, which attack rye, wheat, oats, and barley, not infrequently in quite alarming proportions, as much as 88 per cent of infection having been observed on barley in 1912. Infected seed and infected soil are the chief sources of the disease, while humidity and high temperature are the main factors in the spread of the epidemic. Diseased seed is recognized by the presence of the fungus mycelium in the grains. Positive results were obtained in artificial inoculations of soil, seedlings, and heads with conidia and ascospores and also in artificial inoculations of soil and shoots with the mycelium.

If the infected grain is stored under ordinary conditions for a period of three years, the mycelium completely loses its vitality. Dry heat for 24 hours at 66° C. (150.8° F.) for rye and at 60° for wheat, oats, and barley, while without effect on the vitality of the seed, kills or at least greatly weakens the fungus mycelium imbedded in the grains. Other control measures recommended are seed selection, general sanitation, and proper crop rotation. Soaking of the affected seed in various fungicides was not found to be efficient, except when the spores or the mycelium of the parasites were present on the surface of the grains.

**Glume rust of wheat, P. BERTHAULT** (*Jour. Agr. Prat., n. ser.*, 29 (1916), No. 15, pp. 256, 257).—An unusually severe outbreak of glume rust on wheat is noted as causing much loss to the crop of 1916. Several known cereal rust fungi, their modes of propagation, and protection therefrom are discussed.

**Crown gall of alfalfa in France, G. ARNAUD** (*Jour. Agr. Prat., n. ser.*, 29 (1916), No. 17, pp. 291, 292, fig. 1).—A description is given of alfalfa crown gall and the mode of development and propagation of the causal fungus (*Urophlyctis alfalfæ*), with a short account of the appearance of this disease

in various countries since it was first noted by Lagerheim near Latacunga, Ecuador. There is added a discussion of related species and of diseases, more or less similar, of other plants.

Diseases of asparagus and of melon, G. ARNAUD (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 273-284, figs. 9).—The author reports a study on the fungus causing a disease of young asparagus plants, described as *Melanospora asparagi* n. sp., also on a disease of melon. The conidial form of the latter, previously described under several other names, is supposed to belong to the genus *Fusarium*, the perfect stage of which may be a *Melanospora* found in connection therewith.

Fungus and bacterial diseases of clover, A. A. ĀCHEVSKĪĪ (JACZEWSKI) (*Min. Zeml. [Russia], Biūro Mikol. i Fitopatol., Uchen. Kom. [Pub.]*, 1916, pp. 64, figs. 25).—The author gives a list and descriptions of about 30 distinct diseases affecting the clover plant in Russia.

The majority of these are more or less known in the United States but special attention is called to two parasitic diseases, namely, a crown rot due to *Fusarium trifolii* n. sp., and a blossom mold caused by *Ādocephalum (Botrytis) anthophilum* n. sp. The mycelium of the latter parasite penetrates the seeds, thus carrying the disease from year to year and making its control difficult.

The blossom mold canker (*Sclerotinia trifoliorum*) and anthracnose (*Glæosporium caulivorum*) are considered the most serious troubles of clover and are widely distributed throughout the country. Rusts and leaf spots, although quite prevalent, do not cause material damage. Control measures, general as well as specific to individual diseases, are briefly mentioned. A list of 28 saprophytes, frequently associated with the diseased tissues, is appended, in order to assist observers in recognizing the primary cause of the trouble.

A new disease of the flowers of red clover and its relation to seed production, A. S. BONDARTSEV (BONDARZEW) (*Zap. Sta. Isp. Sĕm. Imp. Bot. Sad. (Ann. Samenprüf. Anst. K. Bot. Gart. Peter Grossen)*, 2 (1914), No. 3, pp. 23, pls. 3, figs. 6).—The author reports on a fungus attack on the flowers of the red clover. The cause of the trouble is said to be *Botrytis anthophila* n. sp. The mycelium permeates the entire plant, growing intercellularly, and it produces its conidia in the anthers of the flowers, causing abnormal pollen grains of low germinative power. The mycelium has also been found within the seed coats, indicating that the disease may be seed-borne. Infected plants produce less seed than normal ones, and its specific weight is somewhat lower, but the germination of diseased seed was higher than that of sound seed. The forage production of the plants was not found to be influenced by the fungus.

A technical description of the fungus is given.

Relation of soil temperature to infection of flax by *Fusarium lini*, W. H. TISDALE (*Phytopathology*, 6 (1916), No. 5, pp. 412, 413).—In connection with an experimental study of flax wilt, the author has determined that the critical temperature for infection of flax by *F. lini* is about 15 to 16° C. (59 to 60.8° F.).

[Report of the assistant in plant pathology], J. H. MUNCIE (*Michigan Sta. Rpt.* 1916, pp. 276, 277).—A brief account is given of work carried on by the author on control measures for anthracnose and blight of beans. Attention is also called to a stem disease of beans that has caused serious damage to the crop. The stem is attacked at the first node, the plant is girdled, and it usually breaks over when the beans are about half mature. This disease is receiving further study.

Celery leaf spot (*Gard. Chron.*, 3. ser., 60 (1916), No. 1556, p. 196).—In a summary of results of recent experimentation regarding the prevention and control of leaf spot of celery, which is said to have been particularly prevalent

in England this year, it is stated that, while hydrogen peroxid proves efficacious in this connection, it is unstable, deteriorating if kept. Corrosive sublimate of 0.1 per cent strength, used to soak the seed for half an hour (after softening for an equal period in warm water), is very successful. If infection appears on careful daily scrutiny during the growth of the plant, Bordeaux mixture should be used, after removal of the leaves most affected. As spores of the fungus (*Septoria petroselini apii*) do not survive for more than two or three years, seed of such age is fairly safe, if germinable.

A collar disease of pea, F. GUÉGUEN (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 302-309, figs. 15).—The author reports a study of a pea disease in the neighborhood of Paris, ascribed to a *Fusarium* said to have been considered by van Hall (E. S. R., 15, p. 375) as the conidial form of *Neocosmospora vas-infecta pisi*. He discusses the character of the lesions, the microscopic aspects of the fungus, its culture, and its capacity for infection.

The reappearance of *Phytophthora infestans* during the growth of the potato plant, J. ERIKSSON (*Compt. Rend. Acad. Sci. [Paris]*, 163 (1916), No. 4, pp. 97-100).—Giving the results of recent studies, the author states that the blight fungus, *P. infestans*, does not appear for three or four months after planting, or until about the time when the blooms appear. In Sweden, the time of the primary outbreak in open fields may vary from the middle of July to the first of September, according to meteorological conditions. Moist weather favors the disease, which very quickly becomes general. The spots appear to be independent of each other. Under glass, if the tubers are planted in January the blight may appear by the middle of April, when the plants are as fully developed as those in the open fields late in summer, causing some check to growth and some deformation of the plants.

The changes occurring within the first day in the development of the parasitic organism, from the supposedly symbiotic or mycoplasmic stage, are described in some detail.

A *Melanconium* parasitic on the tomato, W. H. TISDALE (*Phytopathology*, 6 (1916), No. 5, pp. 390-394, figs. 3).—A more detailed account is given of a disease of tomatoes which has been previously noted (E. S. R., 36, p. 49).

In connection with this study, a *Melanconium* morphologically identical with the tomato parasite was found growing saprophytically on onions in the same greenhouse. The specific identity of the fungus has not been determined, but should the disease become of economic importance, it is expected that further study of the organism would be made.

The results of the experiments show that the fungus grows readily on tomato fruits when introduced through wounds, and that it is also able to attack uninjured fruits if the moisture conditions are suitable for germination and growth. There is said to be some indication that the disease is spread in the greenhouse by white flies.

A parasitic saccharomycete of the tomato, A. SCHNEIDER (*Phytopathology*, 6 (1916), No. 5, pp. 395-399, figs. 4).—The author reports having isolated, from tomatoes obtained in a restaurant in Berkeley, Cal., an organism which proved to be a saccharomycetous ascomycete. The affected tomato presented a slightly depressed area of about 2 cm. in diameter and of a peculiar dull, reddish-brown color. The epidermal tissue was somewhat shriveled, but the hypodermal tissue as well as the parenchymatous tissue underneath appeared nearly normal.

The fungus is a true parasite, as it develops in and on living tissues but will not develop in the presence of decay. Upon the death of the tomato tissues, the organism at once enters upon a very active spore formation.

A note on *Phytophthora infestans* occurring on tomatoes, S. P. WILTSHIRE (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta.*, 1915, pp. 92, 93).—A

fungus attacking severely tomato stems and finally the whole plant showed no external differences from *P. infestans* on potato, but it gave only a slight degree of infection on potato plants, *P. infestans* from potato produced no infection on tomato, the form appropriate to which is thought to be a physiological differentiated strain of *P. infestans*.

**Spraying and dusting tomatoes, F. D. FROMME and H. E. THOMAS** (*Virginia Sta. Bul.* 213 (1916), pp. 3-14, figs. 3).—Continuing previous work (E. S. R., 25, p. 548), the results are given of a comparative study of the efficiency of different spray materials and especially of some fungicides applied in the dust form for the control of the leaf spot (*Septoria lycopersici*) and the late blight (*Phytophthora infestans*) of tomatoes. The fungicides used were 4:5:50 Bordeaux mixture, superfine sulphur to which arsenate of lead was added, and two proprietary fungicides.

The results obtained show that none of the fungicides gave satisfactory control of the Septoria leaf spot, only about 15 per cent increase in uninfected leaves being noticed for the sprayed plants over the checks infected with the fungus. For the late blight and fruit rot, both the liquid and dust applications proved effective for controlling the diseases. Sulphur applied in dry form was the least effective of all the materials used. No foliage or fruit injury was produced by any of the applications.

**Dusting and spraying nursery stock, V. B. STEWART** (*New York Cornell Sta. Bul.* 385 (1917), pp. 335-361, figs. 9).—Preliminary investigations having given very successful results for the control of various leaf diseases of nursery stock by dusting (E. S. R., 34, p. 747), the author conducted further trials in 1916 on a more extensive scale, in which a dust mixture composed of 90 parts of finely ground sulphur and 10 parts of powdered arsenate of lead was employed in an attempt to control the leaf blotch of horse chestnut, leaf spots of currant, plum, cherry, and quince, apple scab, and mildew of rose.

The results obtained show that, if properly applied, dust sprays will control these diseases in the nursery. The dusting method is considered slightly more expensive, but the applications of the dust mixture can be made in a much shorter time and more thoroughly than can spraying mixtures applied with the usual machines employed by nurserymen.

**A black rot of apples, G. T. SPINKS** (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta.*, 1915, pp. 94-96).—In cases of rot showing different colors apparently corresponding purely to differences in variety of the apples affected with *Monilia fructigena*, it is suggested that the color relation depends upon the tannin content or upon the mechanical texture of the apple, but further investigations on this point are in progress.

**A spot disease of apples, B. T. P. BARKER** (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta.*, 1914, pp. 97-99).—A brief description is given of a spot disease noted in the winters of 1913 and 1914 as prevalent on certain varieties of apples grown at the institute. It is said to resemble in some ways Jonathan spot and bitter pit of apples in the United States. Microscopic examination shows fungus hyphæ which kill neighboring cells but do not penetrate deeply. The identity of the causal organism has not been determined. There appears to be some penetration of the cuticle by the fungus hyphæ, especially at weak spots. Internal conditions do not appear favorable to the continued development of the fungus.

**Fungus and other diseases of stone fruits, G. P. DARNELL-SMITH and E. MACKINNON** (*Agr. Gaz. N. S. Wales*, 26 (1915), Nos. 7, pp. 589-598, pls. 8; 9, pp. 749-753, figs. 4).—Notes are given on peach leaf curl (*Eroascus deformans*), brown rot (*Monilia fructigena*, the conidial stage, *Sclerotinia fructigena*, the ascigerous stage, being unknown in Australia), rush (*Puccinia*

*prunispinosæ*), and peach freckle, black spot, or scab (*Cladosporium carpophilum*), as regards their relations, behavior, and control.

Plum diseases, E. RABATÉ (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 341-346).—This is a brief account of observations regarding brown rot (*Monilia cinerea*) of plum, which was followed by plum pockets (*Euxoascus pruni*), resulting in serious loss in the neighborhood of Agen.

Comparative tests with fungicides against grape downy mildew, G. CARUSO (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5. ser., 12 (1915), No. 2, pp. 150-155).—Tests carried out during the months of May to July, 1914, as described in connection with rainfall, are said to show that about the same protection against grape downy mildew is given by nine sprayings with a 1 to 1.5 per cent preparation of a copper product, recommended by the electrical and electrochemical society of Caffaro, as by the same number of sprayings with a 0.5 to 1 per cent Bordeaux mixture.

Second series of comparative tests with fungicides against grape downy mildew, G. CARUSO (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5. ser., 13 (1916), No. 2, pp. 47-55).—The work above noted was continued in 1915, the frequency and abundance of precipitation necessitating 10 treatments extending from May 12 to August 11. A degree of superiority of Bordeaux mixture at 0.5 to 1 per cent over the competing compound at concentrations lower than 1 to 1.5 per cent was again demonstrated.

A bacterial disease of the gooseberry, B. T. P. BARKER and O. GROVE (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta.*, 1915, pp. 97-99).—Specimens of gooseberry bushes diseased in a peculiar manner were found to contain an organism apparently identical with that described in connection with a disease of pear (*E. S. R.*, 33, p. 148). The outbreaks may be conditioned by such factors as the influence of weather on susceptibility.

A new remedy for American gooseberry mildew, I. E. BARBARIN (*Reprint from Zap. Simferopol. Otd. Imp. Ross. Obsch. Sadov.*, No. 157 (1915), pp. 10).—The author has continued his studies (*E. S. R.*, 34, p. 842) of arsenical compounds as fungicides. The results of field spraying experiments with sodium arsenate in 1915 fully corroborated the positive evidence previously secured in laboratory studies. Four applications of this compound, one before, three after the blossoming period, with intervals of from 10 to 20 days, held in check the gooseberry mildew (*Sphaerotheca mors-uvæ*).

The author recommends making the spraying solution not stronger than 1 gm. of sodium arsenate to 3 liters of water, and solutions of 0.5 to 0.75 gm. in the same amount of water are considered preferable. There seems to be very little danger of burning the leaves of the gooseberry plant. As this danger is quite serious in case of some other plants, the use of sodium arsenate for these is not recommended until definite methods are discovered to prevent burning of the leaves.

Studies on diseases of mulberry in 1913, G. ARNAUD and C. SECRÉTAÏN (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 233-265, figs. 19).—This is a report of studies regarding mulberry gummosis (*Bacterium mori*), leaf rust (*Cylindrosporium mori*), dieback (*Nectria cinnabarina*), sclerotium disease (*Sclerotinia libertiana*), a root disease showing symptoms analogous with those of the root rot due to *Armillaria mellea* (which is also described as destructive), and a dropsy or gummosis of the trunk sometimes showing concretions of oxalate of lime crystals, along with other factors influencing diseases of mulberry.

"Canker" and "dieback" disease of mulberry, E. S. SALMON and H. WORMALD (*Gard. Chron.*, 3. ser., 60 (1916), No. 1548, pp. 95, 96, figs. 3).—A description is given of a dieback of mulberry twigs due to their being partly or

wholly ringed by a fungus which is said to be *Fusarium lateritium*. This has been hitherto regarded as a harmless saprophyte.

**Eelworm in daffodils**, A. J. BLISS (*Gard. Chron.*, 3. ser., 60 (1916), No. 1547, pp. 83, 84).—The author cites experiences which are thought to justify the belief that the disease of narcissus bulbs attributed by Massee to *Fusarium bulbigenum* (E. S. R., 30, p. 354) is really due, at least in large part, to the nematode *Tylenchus devastatrix*. He advises the use of a light, sandy soil known to be free from nematodes, good cultivation and drainage, avoidance of farmyard manures, careful examination of bulbs before setting, careful handling, shallow planting, and removal of all suspected bulbs.

**Leaf spot rot of pond lilies caused by *Helicosporium nymphæarum***, F. V. RAND (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 6, pp. 219-232, pls. 4).—An account is given of an irregular spotting and decaying of leaves of pond lilies, which was first noticed in the spring of 1913. The causal organism has been isolated and its pathogenicity demonstrated by successful inoculation into 9 species of *Nymphæa*. The fungus is described as a new species under the name *H. nymphæarum*.

Spraying experiments with ordinary Bordeaux mixture and soda Bordeaux mixture have been conducted with successful results on a commercial scale.

**Studies on chestnut tree diseases**, V. DUCOMET (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 101-108, figs. 3).—Discussing the geographical distribution and extension of the disease called black canker, its causation, and protective measures, the author expresses doubt as to its being caused exclusively by *Melanconis modonia* (*M. perniciosa*) and its *Coryneum* form, as a disease apparently comparable is associated with *Cylodiplospora castanea*.

Treatment of the soil by disinfecting it with carbon bisulphid and by the addition of chemical fertilizers failed to check the progress of the disease, but cutting away the diseased upper portion of a tree infected with *Coryneum* apparently stopped its progress. It is thought that *Melanconis* is not primarily the causative parasite. Of the Japanese varieties showing resistance to black canker, two proved to be susceptible, though in different degrees, to oak tree *Oidium*.

**Black canker of chestnut and the restoration of the chestnut**, A. PRUNET (*Ann. Serv. Epiphyties, Mem. et Rap.*, 2 (1913), pp. 67-100, figs. 5; *abs. in Alpe [Italy]*, 2. ser., 3 (1916), No. 6, pp. 168-177, fig. 1).—The author gives an account of the parasitic character and the effects of black canker, ink disease, or black root of chestnut. This has been known in northern Italy since 1842 and since noted throughout a large part of Mediterranean Europe and as far west as the Azores, but probably not in Asia Minor or Africa. The author discusses the attempts made to restock areas where the chestnuts have been destroyed, by use of the common chestnut and of Asiatic (particularly Japanese) species which appear more or less resistant to this disease; also by the use for stocks of other trees resistant to black canker.

**A method to induce sporulation in cultures of *Botryosphaeria berengeriana***, J. MATZ (*Phytopathology*, 6 (1916), No. 5, pp. 387-389, fig. 1).—The author states that *B. berengeriana* seldom forms spores in ordinary cultures. It was discovered that by sterilizing and inoculating pieces of pecan twigs and covering these with paraffin after inoculation pycnidia containing pycnosporos were readily produced.

**Phacidium infestans on western conifers**, J. R. WEIR (*Phytopathology*, 6 (1916), No. 5, pp. 413, 414).—The author reports the occurrence of *P. infestans* on *Abies grandis*, *A. lasiocarpa*, *A. concolor*, and *Pseudotsuga taxifolia*, and states that in the Western Hemisphere it seems to occur chiefly between the fortieth and forty-fifth degrees of latitude. In Sweden it is stated that the

fungus rarely occurs below the sixtieth degree of latitude. So far the fungus has not been discovered in forest nurseries, but from the fact that natural reproductions succumb very readily to attack it is considered a possible menace in all nurseries where firs are grown.

*Pinus ponderosa* and *P. jeffreyi*, hosts for *Razoumofskyia americana*, J. R. WEIR (*Phytopathology*, 6 (1916), No. 5, p. 414).—In addition to *P. contorta* and *P. banksiana*, the author reports the above species as host plants for this dwarf mistletoe.

A preliminary report on the occurrence of western red rot in *Pinus ponderosa*, W. H. LONG (*U. S. Dept. Agr. Bul. 490* (1917), pp. 8).—A more extended account of investigations already noted (E. S. R., 35, p. 655).

### ECONOMIC ZOOLOGY—ENTOMOLOGY.

Nematode parasites of mammals of the orders Rodentia, Lagomorpha, and Hyracoidea, M. C. HALL (*Proc. U. S. Nat. Mus.*, 50 (1916), pp. 1-258, pl. 1, figs. 290).—This systematic work includes descriptions of 2 superfamilies, 5 subfamilies, 1 tribe, 8 genera, and 11 species new to science. A list of hosts and their parasites, a bibliography of 16 pages, and a complete index are included.

Diagnosis of plague in rats, C. L. WILLIAMS (*Pub. Health Rpts. [U. S.]*, 31 (1916), No. 33, pp. 2199-2205).—"In the presence of an epizootic of plague, macroscopic examination alone for the detection of rodent plague results in appreciable error; the microscopic examination of smears should therefore be employed as a supplement to the naked-eye diagnosis of rodent plague when the epizootic declines. This error is greater toward the end of an epizootic and is of particular importance when eradication measures are being employed. By routine examination of smears a materially important number of infected rats may be discovered that would otherwise pass undetected."

Propagation of wild duck foods, W. L. McATEE (*U. S. Dept. Agr. Bul. 465* (1917), pp. 40, figs. 35).—This bulletin supersedes Biological Survey Circular 81 and Department Bulletin 58, previously noted (E. S. R., 25, p. 757; 30, p. 545).

Report of the entomological department, J. TROOP (*Indiana Sta. Rpt. 1916*, pp. 41, 42).—In observations made in breeding cages and in the orchard with the codling moth it was found that the moths did not appear at any definite time but extended over a period of more than two weeks. In examinations made of orchards of progressive fruit growers it was found that they had practically no trouble with the codling moth, thus indicating that the trouble which certain growers experienced was local and probably due to faulty spraying.

An outbreak of flea beetles on corn took place in Orange County and the southern part of Lawrence County, the corn being attacked when from 2 to 4 in. in height.

In experiments with washing powders as insecticides it is stated that Pearlina and Snow Boy both spread well, kill all aphids hit, and do not injure the plants. It is recommended that Pearlina be used at the rate of two tablespoonfuls to a pint of water and Snow Boy at the rate of one tablespoonful to a pint of water.

Report of the south coast laboratory, E. G. SMYTH (*Rpt. Bd. Comrs. Agr. P. R.*, 4 (1915), pp. 45-50).—This report relates particularly to biological studies at Santa Rita of eight species of scarabeid beetles known to injure sugar cane or to be found in sugar-cane fields in Porto Rico, namely, *Lachnosterna* "grande," *L.* "media," *L.* "pequeña," *Ligyrus tumulosus*, *Strategus titanus*, *S. quadrioveatus*, *Dyscinetus trachypygus*, and *D. barbatus*. The com-

plete life histories of the eight species have been worked out from egg to adult, and a tabular summary is given of the average time in days and the maximum and minimum periods for each stage of the beetles.

It was found during the year that two distinct varieties of *Lachnosterna* "grande" and of *L.* "media" occur on the island. It is said to be necessary to fumigate the holds of the boats bringing cane from the Dominican Republic, due to the fact that in that Republic the leaves of the cane are eaten by the caterpillar of a butterfly (*Calisto archebales*), which is a source of severe injury to the plant.

[Contributions from the phytopathological service at Wageningen] (*Meded. Phytopath. Dienst Wageningen, 1916, Nos. 1, pp. 14, pls. 3; 2, pp. 14, pls. 3; 3, pp. 22, pls. 3*).—These papers relate, respectively, to the twig borer or budworm (*Incurvaria capitella*) of currants, the "red worm" (*Lampronia rubicilla*) of raspberries, and the small winter moth (*Cheimatobia brumata*). Maps showing the distribution of these insects in the Netherlands are included.

[Italian entomological communications] (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 12 (1914), pp. 223-258, 391-418, 475-616, 655-682, 711-720, pls. 3, figs. 117*).—The papers here presented that relate to economic entomology are: Description of a New African Coccinellid (*Serangium giffardi* n. sp.) (pp. 223-236), previously noted (E. S. R., 32, p. 453), and Investigations of an African Phorid (*Aphiochæta xantina*), with Particular Consideration of the External Anatomy of the Larva (pp. 237-258), by G. Grandi; Agriculture and Malaria in the Valley of the Enza, by G. Rossi (pp. 391-418); Contribution to the Knowledge of the Termites of West Africa, by F. Silvestri (pp. 475-616); A Disease of the Larva of *Porthesia chrysorrhæa* in the Province of Campobasso, by B. Majmone (pp. 655-661); Notes on Two Microphagous Coccinellids, *Thea 22-punctata* and *Vibidia 12-guttata* (pp. 663-672), Will the Mediterranean Fruit Fly (*Ceratitis capitata*) Develop in Italian Lemons? (pp. 673-676), previously noted (E. S. R., 35, p. 259), and Some Experiments with *Eccoptogaster* (*Scolytus*) *amygdali*, *E. rugulosus*, and *E. pruni*, Serious Enemies, Respectively, of the Almond, Peach, and Plum (pp. 677-682), by G. Martelli; The Control of *Chrysomphalus dictyospermi pinnulifera* and *Icerya purchasi* in the Province of Messina, by A. Drago (pp. 711-717); and Studies and Observations on the Control of Sooty Mold of Citrus and the Olive by Means of Lime-sulphur in the Province of Messina during 1911, by F. Portale (pp. 719, 720).

Pests of orange trees and other Aurantiaceæ, G. BONDAR (*Insectos Damninhos a' Agricultura.—III, Pragas das Laranjeiras e Outras Auranciaceas. São Paulo: Duprat & Co., 1915, pt. 3, pp. 47, figs. 28; rev. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 6, p. 201*).—This third paper (E. S. R., 30, p. 657) is a summary of information relating to citrus insects in Brazil.

On some animal pests of the Hevea rubber tree, E. E. GREEN (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 608-636*).—A summary of the more important mammal and insect enemies of rubber.

Entomophagous insects and their practical employment in agriculture, A. BERLESE (*Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 3, pp. 321-332*).—A brief review of the subject.

The causes which affect the toxicity of arsenicals employed in agriculture, J. BATTAIL (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 37 (1916), No. 19, pp. 448-452; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 7, pp. 307, 308*).—While the insecticidal value of the arsenical salts in general use in agriculture is proportional to the amount of arsenic they contain, their order of toxicity is modified by the varying degree of solubility and the presence of a toxic metal or of impurities. Their arrangement in order of toxicity and the percentage of

arsenic is as follows: Arsenate of lime 37.9, lead arsenate 16.7, sodium arsenate 36, arsenite of copper 34.5, iron arsenate 33.6, and copper arsenate 32 per cent.

*Termes gestroi* as a pest of the Para rubber tree, H. C. PRATT (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 637-640*).—A brief account of the injury caused by this termite.

[Use of d'Herelle's bacillus (*Coccobacillus acridiorum*) in the control of *Schistocerca peregrina*] (*Ann. Inst. Pasteur, 30 (1916), Nos. 5, pp. 209-242, figs. 11; 7, pp. 319-329, figs. 4; 8, pp. 388-421, figs. 7; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), Nos. 8, p. 351; 10, pp. 410, 411; 11, p. 481*).—The several papers reporting upon the biological method of controlling *S. peregrina* are by Étienne Sergent (p. 209-224) on a trial campaign in the valley of the Upper Tafna, mixed commune of Sebdu (Department of Oran), Algeria—the existence of a natural infection which produced immunity (May, June, and July, 1915); by M. Béguet (pp. 225-242) on a trial campaign in Algeria from December, 1914, to July, 1915, and more particularly in the Barik region (Department of Constantine); by Musso (pp. 319-329) on a trial campaign in the region of Bougzoul-Msiline, mixed commune of Boghar, Algeria, in May and June, 1915; and by H. Velu and A. Bouin (pp. 388-421) on an attempt to destroy *S. peregrina* in Morocco.

The Tingitoidae of Ohio, H. OSBORN and C. J. DRAKE (*Ohio State Univ. Bul., 20 (1916), No. 35, pp. 217-251, figs. 28*).—This synopsis of the "lace-bugs" of Ohio includes descriptions of 2 genera and 11 species new to science. Twenty-two species representing 12 genera are recorded, several of which have not as yet been collected within the State.

Review of the Philippine Membracidae, W. D. FUNKHOUSER (*Philippine Jour. Sci., Sect. D, 10 (1915), No. 6, pp. 365-405, pls. 2, figs. 3*).—This synopsis of the membracids recognized from the Philippines includes descriptions of new genera and species and a bibliography of the literature.

The green bug or spring grain aphid (*Toxoptera graminum*), S. W. BILSING (*Texas Sta. Circ. 13 (1916), pp. 5-8, figs. 2*).—This circular contains information concerning the green bug and its control that is based on observations made during a trip of inspection through the wheat-growing sections of the State during the latter part of January and the first part of February.

Elm leaf rosette and woolly aphid of the apple, *Schizoneura lanigera* (*americana* in part), EDITH M. PATCH (*Maine Sta. Bul. 256 (1916), pp. 329-344, pls. 5*).—This revised edition of Bulletin 217, previously noted (*E. S. R., 30, p. 548*), contains such changes as bring the subject up to date.

A contribution to our knowledge of the white flies of the subfamily Aleyrodinae (Aleyrodidae), A. L. QUAINANCE and A. C. BAKER (*Proc. U. S. Nat. Mus., 51 (1917), pp. 335-445, pls. 46, figs. 10*).—The present paper, a continuation of the the authors' work on the classification of the Aleyrodidae (*E. S. R., 31, p. 755*), includes descriptions of 10 subgenera and 36 species new to science.

The coccid enemies of the vine, J. FEYTAUD (*Bul. Soc. Etude et Vulg. Zool. Agr., 15 (1916), Nos. 1-2, pp. 1-11, figs. 4; 3-4, pp. 21-27, figs. 2; 5, pp. 43-46, figs. 2; 6, pp. 52-54, fig. 1; 7, pp. 65-74; 8, pp. 88-90*).—Of the many coccids noted, *Pulvinaria vitis*, *Lecanium persicæ*, *Targionia vitis*, and *Dactylopius vitis* are the most important in France.

The San José scale, H. R. PAINTER (*Oklahoma Sta. Circ. 41 (1916), pp. 3-7, figs. 3*).—A brief popular account.

The agricultural importance of the mycosis of *Chrysomphalus dictyospermi*, L. SAVASTANO (*R. Staz. Sper. Agrum. e Frutticol. Acireale, Bol. 21 (1916), pp. 8; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 6, p. 222*).—Reports

by citrus growers of the disappearance of *C. dictyospermi* in Calabria led to investigations which showed this to be principally due to the scale being attacked by a fungus of the genus *Cladosporium*.

Problems connected with the new Egyptian cotton pest, *Gelechia gossypiella*, the pink bollworm, L. H. GOUGH (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 385-398*).—Substantially noted from another source (*E. S. R., 35, p. 854*).

Note on a machine to kill *Gelechia* larvæ by hot air, and the effects of heat on *Gelechia* larvæ and cotton seed, L. GOUGH (*Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 6 (1916), pp. 15, pls. 3; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, pp. 472, 473*).—This is a description of a hot-air machine consisting mainly of a furnace for the generation of the hot air, a hot-air chamber through which the seed passes, and a motor. The results of work with the pink bollworm, reported in tables, show that there is ample limit for regulation of the temperature in such a way as to kill the worms without damaging the seed.

Life history of the codling moth in the Pecos Valley, New Mexico, A. I. QUAINANCE and E. W. GEYER (*U. S. Dept. Agr. Bul. 429 (1917), pp. 90, figs. 17*).—This is a report on life history studies of the codling moth conducted by the division of Deciduous Fruit Insect Investigations of the Bureau of Entomology in continuation of those previously noted (*E. S. R., 33, p. 559*). In the work at Roswell, N. Mex., in the Pecos Valley, special attention was given to the biology of the pest during 1912 and 1913 and to extensive spraying operations, but during 1914-15 the work was limited to orchard experiments.

The codling moth produced three generations in this valley during 1912, while in 1913 a partial fourth brood of larvæ developed. In 1912 pupation of the overwintering larvæ began March 15 and continued for about one month, while in 1913 the first pupa was observed March 23 and pupation continued for 51 days. During 1912 the moths of the spring brood appeared April 12 and continued to emerge to May 28. In 1912 oviposition of the spring brood of moths began April 16, continuing 45 days, while in 1913 the first eggs of this brood were noted May 1.

"The time required for first-brood eggs to hatch in 1912 was 9.05 days, with a range of 5 to 13 days, whereas in 1913 eggs of this brood hatched on an average in 5.96 days, with a range of from 4 to 11 days. First-brood larvæ in 1912 fed on an average 21.52 days, and in 1913, 24.45 days. The pupal stage of the first brood in 1912 averaged 12 days, and in 1913, 11 days. Moths of the first brood in 1912 were out June 9 and continued to emerge until July 22. In 1913 first moths were out June 3, the period of emergence lasting until July 10. First-brood moths in 1912 oviposited over an average period of 4.45 days, and in 1913 5.7. The life cycle of the first generation in 1912 required on the average 51.14 days, and in 1913, 46.91 days.

"Second-brood eggs in 1912 averaged 5.62 days for incubation, with a minimum of 4 and a maximum of 8 days. The incubation period of eggs of this brood in 1913 was on the average 4.9, with a minimum of 4 and a maximum of 7 days. The feeding period of second-brood larvæ in 1912 averaged 21.23 days, and in 1913, 19.7 days. The pupal stage for second-brood pupæ in 1912 averaged 11.23 days and in 1913, 11.06 days. The life cycle for the second generation of the codling moth in 1912 averaged 41.26 days, and in 1913, 41.04 days.

"Eggs of the third brood in 1912 averaged 5.75 days for the incubation period, with a minimum of 4 and a maximum of 9 days. In 1913 the incubation period for eggs of this brood averaged 5.36 days. During 1912 third-brood larvæ fed on an average of 26.55 days with a range of from 15 to 56 days, whereas in 1913 the average feeding period for this brood was 20 days, the range

being from 15 to 28 days. The pupal stage of the third brood in 1912 required on an average 14.94 days, with a minimum of 11 and a maximum of 20 days. The average length of this stage in 1913 was 11.4 days, with a minimum of 7 and a maximum of 17 days. The life cycle of the third generation of 1912 required on an average 48.57 days with a range of from 36 to 62 days, and in 1913, 43 days with a range of 34 to 58 days.

"Fourth brood eggs were in evidence in 1913 on August 20, and oviposition continued to September 8. The incubation period, on an average, was 7.9 days. The feeding period of fourth-brood larvæ in 1913 averaged 38.36 days, with a minimum of 25 days and a maximum of 53 days. All of these larvæ passed the winter as such. . . .

"Successful band records were made during 1913 at Roswell, Artesia, Lincoln, and Santa Fe. From available data the conclusion is drawn that at Lincoln there occur two full generations and a partial third, while at Santa Fe, a more northerly location, there appears to be but one complete generation, followed by a partial second."

The results of spraying operations during 1913-14 have been previously noted (E. S. R., 31, p. 252).

*Sorosporella uvella* and its occurrence in cutworms in America, A. T. SPEARE (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 6, pp. 189-194, pl. 1, fig. 1).—This preliminary paper reviews the present status of knowledge of the fungus parasite *S. uvella* (*agrotidis*), records its presence in the United States, and presents some evidence to show that it is not entomophthoraceous.

The form was originally described from Russia in 1886 as *Tarichium uvella*, but there are no records of its occurrence in Europe since 1888. The report by Gibson of its occurrence in Ottawa, Canada, is said to be the only American record (E. S. R., 34, p. 251). The author's observations of its morphology and cultural characteristics here reported are based upon parasitized larvæ and a pupa of a cutworm (*Euxoa tessellata*) collected at College Park, Md., in June and July.

Observations on the *Lestophonus*, a dipterous parasite of the cottony cushion scale, H. S. SMITH and H. COMPERE (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 10, pp. 384-390, figs. 9).—*Cryptochatum monophebi*, popularly known in California as the *Lestophonus*, is an important adjunct in the control of the cottony cushion scale in California. In the present paper the author reports upon the discovery of this parasite in Australia and its introduction into California, its distribution and abundance in California, and its biology. It is common in Los Angeles, Orange, San Diego, Santa Barbara, and Sacramento counties, and fairly so in Santa Clara County. While by nature it is more erratic than *Vedalia*, at times it becomes very abundant, occasionally infesting more than 90 per cent of the scale. There are five or six generations of the parasite during the year.

Observations on the life history of *Pterodontia flavipes*, J. L. KING (Ann. Ent. Soc. Amer., 9 (1916), No. 3, pp. 309-321, pls. 2).—A report of a study of the biology of this dipteran, the larvæ of which parasitize spiders, an epeirid (*Epeira sericata*), and a lycosid, probably *Lycosa pratensis*.

*Anopheles* infectivity experiments.—An attempt to determine the number of persons one mosquito can infect with malaria, M. B. MITZMAIN (Pub. Health Rpts. [U. S.], 31 (1916), No. 35, pp. 2325-2335, pls. 2).—A series of 17 infectivity experiments (E. S. R., 35, p. 759) in which human beings were employed to test the infectibility of *Anopheles punctipennis* with *Plasmodium vivax* resulted in 14 cases of malarial fever. "The sporozoites in the mosquitoes used developed 10 to 22 days after the definitive hosts were given an opportunity to bite a patient harboring a scanty number of mature tertian gametocytes.

"In an attempt to infect several persons with a single specimen of *A. punctipennis*, one mosquito proved to be the sole infective agent in one experiment, and one proved to be the sole infective agent in three experiments. These two specimens when applied to the same person transmitted the infection in five cases, while one of them used with a third mosquito succeeded in infecting four persons.

"In these experimental inoculations it was demonstrated that in nine instances in which two mosquitoes succeeded in transmitting malaria at least one of the pair was capable of causing the disease when used singly. It was demonstrated in 11 experiments that short exposure to bites was sufficient to cause successful transmission of the disease. In all of the successful inoculations only tertian infection was reproduced. *P. vivax* was demonstrated microscopically."

Wireworm control, J. N. FRENCH (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 6, pp. 225-235, figs. 3).—Wireworm injury in the Oxnard district of California is said to be confined from a commercial standpoint almost entirely to the beet and bean crops, \$100,000 being a conservative estimate of the damage done during the season of 1914. The injury during 1915, due to the warm weather which prevailed during the growing season and to the control work, was reduced to about half that amount. *Limonius californicus* was the most injurious species, though at least three others were found associated with it in some instances.

The present paper reports upon control work carried on in this district during the years above mentioned. The work with poison baits proved entirely unsatisfactory. In soil fumigation work it was found that a very small dose of cyanid would kill the pest, provided it was put into the soil below the worms and the top of the ground packed to hold the gas, but the destruction in every case was slow, requiring from three to seven days. There was practically no difference in the action of cyanid in solution and that used in the powdered form, and there was comparatively little difference between the results obtained with the stronger doses and with the weaker ones.

Of the control measures tested, which included the use of poisoned baits and deterrents, soil fumigation, and catch crops against the larvæ, fall plowing against the pupæ, and the straw-trap method for the adult, the author has found the straw method of catching the beetles to be the most promising from the standpoint of permanent success. In combating the worms, the potato catch crop method is recommended in preference to the cyanid method, because it is much cheaper and has also been more thoroughly worked out and tested on a much larger scale. A combination of the straw-trap method working against the beetles and the potato catch crop method against the worms should be especially effective.

Powder-post damage by *Lyctus* beetles to seasoned hardwood, A. D. HOPKINS and T. E. SNYDER (*U. S. Dept. Agr., Farmers' Bul.* 778 (1917), pp. 20, figs. 13).—This publication describes methods which have been found effective in preventing the losses caused by *Lyctus* beetles, with a view to inducing a more general adoption of them throughout the country, as well as to show the character and extent of the damage. A revision of the family, including notes on their habits, has previously been noted (*E. S. R.*, 25, p. 261).

Foul brood regulations, F. B. PADDOCK (*Texas Sta. Circ.* 14 (1916), pp. 3-5).—These regulations, which supplement those of Circular 11 previously noted (*E. S. R.*, 34, p. 657), became effective on September 1, 1916.

The Texas foul brood law and foul brood regulations, F. B. PADDOCK (*Texas Sta. Circ.* 17 (1916), pp. 20).—This circular brings together the text of the Texas foul brood law and the several regulations since promulgated,

including those which became effective on March 1, 1917, thus superseding Circulars 8 and 11 (E. S. R., 34, pp. 454, 657) and Circular 14 noted above.

The Cresson types of Hymenoptera, E. T. CRESSON (*Mem. Amer. Ent. Soc. No. 1 (1916), pp. 141*).—This paper contains a complete list of the species of Hymenoptera described by the author, arranged alphabetically under each family, with reference to the original description, sex, number of the type specimen, locality and condition of the specimen, etc. Types of 2,737 species are given in the list. A list of the entomological writings of the author arranged in chronological order is appended.

*Tetrastichus bruchophagi*, a recently described parasite of *Bruchophagus funebris*, T. D. URBAINS (*U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 7, pp. 277-282, pl. 1*).—This is a report of studies made in California of *T. bruchophagi*, described by Gahan (E. S. R., 31, p. 355), which is the most important of several new parasites which attack *B. funebris* in alfalfa seed (E. S. R., 32, p. 454) throughout the alfalfa seed-growing districts of central California. *T. bruchophagi* is a parasite of considerable importance in these districts, having destroyed in 1913 about 52 per cent of the chalcis fly larvæ infesting alfalfa seed. This parasite is known to occur in other States as far east as Virginia.

While normally an external parasite it has in several instances been found completely inclosed within the host larva. It has not been observed to parasitize the pupal stage. This parasite hibernates in the larval stage within infested seeds of alfalfa in which it has attacked its host. It appears to be the first parasite of this host to appear in the fields in early spring, and is one of the first to transform to the pupal stage and emerge as adult with the approach of warm spring weather.

The eggs are deposited on the surface of the host larva, the ovipositor being forced into the seed pod and infested seed. Under the most favorable conditions the development of the larva does not require more than 10 days, the prepupal stage about 48 hours, and the pupal stage an average of 17.7 days. Where conditions are favorable there are from two to four generations in a single season, although under the less favorable hot and dry desert conditions the species frequently has only a single generation in a season.

Note on *Rhogas kitcheneri*, L. H. GOUGH (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 433, 434, pls. 2*).—A report of further observations of this parasite of *Earias insulana* and *Ephestia cautella* (E. S. R., 32, p. 156).

Structure of the egg and early stages of development in some hymenopterous parasites, F. SILVESTRI (*Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 10 (1915), pp. 66-88, pls. 6, figs. 3; abs. in Jour. Roy. Micros. Soc., No. 3 (1916), pp. 290, 291*).—The author reports studies made of five species of Chalcididae, namely, *Encyrtus mayri* which parasitizes the eggs of the lepidopteran *Oecophyllembius neglectus*; *Encarsia partenopea* and *Prospattella (Doloresia) coniugata* which parasitize species of Aleyrodes; *P. berleseii* which parasitizes the female of the West Indian peach scale; and *Anaphoidea luna* which parasitizes the eggs of *Phytonomus variabilis*.

## FOODS—HUMAN NUTRITION.

Changes in fresh beef during cold storage above freezing, R. HOAGLAND, C. N. MCBRYDE, and W. C. POWICK (*U. S. Dept. Agr. Bul. 433 (1917), pp. 100, figs. 2*).—The investigation here reported was undertaken to study the changes in fresh beef when stored at temperatures above freezing, with special reference to the effect of such changes upon the wholesomeness of the product; to determine the causes of the changes taking place under the above conditions; and to

determine the length of time that fresh beef could be held in cold storage at temperatures above freezing and remain in wholesome condition. Three distinctive lines of investigation were planned—autolysis experiments with fresh beef, cold-storage experiments with fresh beef, and a study of the factors affecting the length of time that beef could be held in cold storage.

The results of the aseptic autolysis experiments showed the following: Physical changes were not marked and consisted chiefly of a slight softening of the tissues, an exudation of juice, and a change in color of the meat. Total soluble extract or total solids decreased early in the experiments and later increased, while the ash of the extract showed appreciable although not regular increases, which corresponded roughly with similar increases in the total soluble phosphorus. The acidity of the samples showed appreciable increases toward the close of the experiment. The changes taking place in the nitrogenous compounds consisted in general of an increase of total soluble nitrogen and a conversion of the higher forms of soluble nitrogen compounds into simpler combinations. Appreciable increases were noted in total soluble phosphorus and in soluble inorganic phosphorus, together with corresponding decreases in insoluble and in soluble organic phosphorus. There was no development of free hydrogen sulphid during the course of the experiment.

The cold-storage experiments with fresh beef included bacteriological and histological studies and also physical and chemical studies of the meat during storage. The following conclusions are drawn from the bacteriological and histological tests:

"Certain bacteria (chiefly micrococci) may be normally present in the carcasses of healthy animals slaughtered for beef. These bacteria possess no pathological significance and do not appear to multiply in the cold-stored carcasses, provided the cold-storage room is maintained at the proper temperature. Bacteria and molds grow on the surface of cold-storage carcasses but do not penetrate to any great depth (less than 1 in. in 177 days); bacteria apparently are not concerned in the changes leading to increased tenderness in cold-stored meats. Microscopic sections failed to show any noticeable histological changes in the muscular tissue after 77 days of storage."

"The chemical changes that took place in the muscular tissue of beef held in cold storage at temperatures above freezing for periods ranging from 14 to 177 days consisted chiefly in increases in acidity; in proteose, noncoagulable, amino, and ammoniacal nitrogen; and in soluble inorganic phosphorus; while decreases occurred in coagulable nitrogen and in soluble organic phosphorus. On the whole these changes were of a progressive nature. The chemical changes that took place in the fatty tissues of the beef consisted chiefly in marked increases in the acidity of the kidney and external fats."

These changes were similar in nature to, but less in extent than, those caused by enzymatic action when lean beef underwent aseptic autolysis for periods ranging from 7 to 100 days.

"The chemical changes that took place in the muscular tissue of the beef during storage were without appreciable effect either upon the nutritive value or the wholesomeness of the edible portions of the product; but the changes that took place in the kidney fat and external fatty tissue after the longer periods of storage rendered them unsuitable for human consumption. . . .

"The chemical changes which took place in the muscular tissues of the beef during storage may be regarded as largely due to enzym action.

The principal effect of storage upon the organoleptic properties of the beef was a marked increase in tenderness of the meat. This change did not appear to progress appreciably after the beef had been held in storage for from two to four weeks. While the flavor also changed, individuals would

probably not agree as to whether the change was in the nature of an improvement or a deterioration.

"On the whole it would appear that the chemical changes that occurred during the storage of beef in these experiments did not appreciably affect the nutritive value of the meat when the period of storage was limited to that customarily employed in commercial practice. Indeed, even when the period of storage was greatly prolonged, evidence is lacking to show that the nutritive value of the meat was diminished. Yet, in view of the more extensive chemical changes that took place during the longer periods of storage and on account of the deficiency of our knowledge regarding the nutritive values of the various cleavage products, it is by no means impossible that the nutritive value of beef may be decreased by unduly long periods of storage. . . .

"Beef was held in cold storage at temperatures above freezing in an experimental cooler for as long as 177 days, whereas it was possible to hold beef in storage in a cooler in a modern packing house for only 55 days. The shorter storage period in the second instance was due to the much higher humidity of the packing-house cooler as compared with the experimental cooler.

"The length of time that fresh beef can be held in cold storage at temperatures above freezing and remain in wholesome condition is dependent upon a number of factors, among which the temperature and humidity of the storage room and the character of the beef are of the most importance.

"In light of the various factors that affect the length of time that fresh beef can be held safely in cold storage at temperatures above freezing, it is clearly impracticable to attempt to insure the wholesomeness of the product merely by limiting the duration of storage. The wholesomeness of cold-stored beef must be judged by other considerations besides the length of time that the product has been held in cold storage."

Eggs and their value as food, C. F. LANGWORTHY (*U. S. Dept. Agr. Bul. 471 (1917), pp. 30, figs. 3*).—This bulletin summarizes data regarding the nature, food value, and uses of eggs, and the effects of handling, storing, and marketing eggs upon their value in the household. It is essentially a revision of Farmers' Bulletin 128 (*E. S. R., 13, p. 166*), the material contained therein having been brought up to date and presented in a somewhat different form.

Practical milling tests, E. F. LADD (*North Dakota Sta. Circ. 15 (1917), pp. 11, figs. 4*).—This investigation was carried on to determine whether or not the milling tests made with the experimental mill at the college represented the results which are obtained in the commercial milling of wheat. Data are given regarding the milling of wheat at a small commercial mill doing a grist business and also regarding comparative milling and baking tests made at the station on samples of wheat obtained from the mill.

It was found that the results at the commercial grist mill did not differ materially from those at the experimental mill. The higher percentage of total flour obtained at the experimental mill was ascribed to the better cleaning-up at the end of each cut-off than in the case of the commercial grist mill.

The distribution of chlorin in cereals and dry legumes, BALLAND (*Jour. Pharm. et Chim., 7. ser., 15 (1917), No. 4, pp. 105-107*).—The experimental method by which chlorin in cereals and dry legumes was determined is briefly described. Data are given regarding the chlorin content of a number of cereals and dry legumes.

Recipes for the preparation of the dasheen (*U. S. Dept. Agr., Bur. Plant Indus. [Circ.], 1916, pp. 4*).—Suggestions are given for the preparation of dasheens, together with a compilation of recipes.

[Food and drug inspection], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 4 (1917), No. 10, pp. 243-253, fig. 1).—Analytical data are reported regarding several samples of miscellaneous foods and drugs. The results are reported of the inspection of grocery stores, meat markets, restaurants, etc., and miscellaneous information regarding various pure-food topics is included.

Eighth annual report of the board of food and drug commissioners (*Ann. Rpt. Bd. Food and Drug Comrs. R. I.*, 8 (1916), pp. 35).—The work of the commission during the year ended December 31, 1916, is summarized. It included the inspection of a large number of samples of miscellaneous foods and drugs.

Report of the Dairy and Food Department [of Iowa], W. B. BARNEY (*Rpt. Dairy and Food Dept., Iowa, 1916*, pp. 72, figs. 12).—This publication reviews the work of the department for the year ended October 31, 1916. This included the examination of 4,479 samples of foods, drugs, stock feeds, paints, and oils; the examination of 14,356 samples of milk and cream; and the inspection of a large number of establishments where foods are prepared and sold, as well as the routine inspection of weights and measures. The publication contains considerable information on the relative value and cost of different foods and a report of the work of the Iowa State Dairy Association for 1916.

A discussion of a simple steam sterilizer for farm dairy utensils is also included. Directions are given for the construction and operation of this sterilizer.

A summary of the market situation in Boston, P. T. CHERINGTON ET AL. (*Boston City Doc. 118* (1916), pp. 175, figs. 19).—This is a preliminary report of the Market Advisory Committee to the Boston City Planning Board. It includes a summary of the work done, and embodies several suggestions for detailed study along three lines, which include investigations of a general nature, a study of retail markets, and a study of wholesale markets, including terminal problems.

The appendix of the report contains the following material: Sources of and Methods of Handling Perishable Food Products in the Boston Market, by T. C. Huff and W. E. Lushy; Summary of Some of the Main Features of the Organization of Boston's Fruit and Produce Trade, by T. C. Huff; A Study of a Public Market System for Boston, by E. D. Pratt, C. P. Putnam, and E. A. Teeson; A Study of the Eight Agencies by Which the Perishable Food Supply of Boston is Retailed, by the Women's Municipal League, Mrs. W. M. Wheeler, assisted by Suzanne Wunderbaldinger and numerous investigators; and A Study of Some of the Effects of Cold Storage on the Egg Trade of Boston, 1904-13, by A. C. James. It also contains tables of miscellaneous statistics regarding food receipts, food prices, eggs, cold-storage data, etc.

The report is concluded by a bibliography compiled by C. C. Williamson, which includes 28 pages of references on markets and marketing, cost of living and food prices, municipal slaughterhouses and meat supply, cold storage of food products, transportation and distribution of food products, and cooperation, with special reference to food products; and an outline of study adopted by the subcommittee as its plan of work.

Education in economy [of foods], C. A. SPOOLER (*Pomona, Cal.: Author, 1917*, pp. 248, pls. 22).—This book contains information regarding the selection of meats, poultry, fish, and provisions, together with suggestions regarding their preparation for the table. The book is illustrated by a number of plates showing the different cuts of meat.

Planning of meals, LELIA MCGUIRE (*Agr. Col. Ext. Bul. [Ohio State Univ.]*, 12 (1916-17), No. 3, pp. 16).—A popular treatise on food requirements and food selection for variety, which contains suggested menus.

Misguided appetite and the high cost of living, A. E. PERKINS (*Mo. Bul Ohio Sta.*, 1 (1916), No. 12, pp. 363-370, fig. 1).—A more or less popular article dealing chiefly with the food requirements of the body and the use of milk and skim milk in the diet.

Electrical cooking and heating, EDNA GROVES (*Jour. Electricity*, 38 (1917), No. 4, pp. 116-118, fig. 1).—This article discusses essentially cost data.

[Report of the] nutrition laboratory, F. G. BENEDECT (*Carnegie Inst. Washington, Year Book 15* (1916), pp. 273-285).—The work of the laboratory during the year 1916 is reviewed. Various additions to the laboratory equipment are described and brief outlines are given of the investigations in progress. The latter include a study of metabolism during muscular work, metabolism in rectal feeding with alcohol and simple sugars, the influence of moderate amounts of alcohol on psychological processes, metabolism in diabetes, metabolism of normal infants, influence of environmental temperature on metabolism, etc. A list of the publications issued by the laboratory during the year is given, together with brief abstracts of the same.

On the rôle of organic acids in the process of peptic digestion, I. V. BELGOWSKY (*Zap. Selsk. Khoz. Inst. Imp. Petra I (Mem. Inst. Agron. Emp. Pierre I)*, 1 (1916), pp. 70-100).—This publication reports experiments carried out to determine whether or not an acid medium is necessary for a normal course of digestion and whether the activity of the peptic ferment is possible only in the presence of acids. It was also desired to obtain some information on the rôle of the various acids in digestion.

From the experimental data reported the conclusion is drawn that lactic, butyric, propionic, acetic, and valerianic acids, present in the digestive juice in a quantity corresponding to 0.25 per cent of hydrochloric acid, can not replace the latter. With reference to the influence of organic acids on pepsin, it is stated that the acids are more or less passive as regards albumin, and in some cases butyric acid decreases the activity of the pepsin.

Pellagra (*Kansas City, Mo.: Burton Publishing Co., 1916, pp. 362, figs. 49*).—The first part of this publication contains a contribution to the etiology and pathogenesis of pellagra by G. Alessandrini and A. Scala, which has been translated from the Italian by E. M. Perdue. This reports the results of animal experiments and other data, from which the authors concluded that pellagra "is the effect of a chronic intoxication which is caused by silica in colloidal solution in water of determinate composition, and, therefore, may be also defined as a disease caused by colloidal minerals."

The second part of the publication is a review of the pellagra situation in the United States, which is considered from the theory of colloidal silica brought out in the earlier part of the publication. The subject matter of this book is not in accordance with the generally accepted results of workers on pellagra in this country.

Studies in pellagra (*Pub. Health Serv. U. S., Hyg. Lab. Bul. 106* (1917), pp. 5-102, pls. 7).—Three papers are presented.

I. *Tissue alteration in malnutrition and pellagra*, by J. Sundwall (pp. 5-73, pls. 7).—The results are reported of the examination of tissue obtained at necropsies of pellagrins and of tissue obtained at autopsies of certain animals which had been fed various diets with a view to producing, if possible, symptoms and tissue changes which are found in pellagra. The conclusion is drawn from these observations that the tissue alterations, including the degenerative changes in the nervous system occurring in the animals as a result of malnutrition, were strikingly similar to those observed in pellagrous tissue. The author states that there could be no objection from a pathological standpoint to the classification of pellagra along with rickets, scurvy, and beri-beri as a

dietary disease. Rigid examination of tissues from pellagrins revealed no micro-organism that could be regarded as a specific etiological factor.

"Pellagra, then, possesses no characteristic cell alterations, but the pathological changes are those resulting from malnutrition. Consequently, it is erroneous to assume that certain substances such as silicates, aluminates, etc., are the etiological factors of pellagra, as some have done, because of the pathological changes that have been induced as a result of the administration of these substances. . . .

"The pathological changes in tissues in malnutrition are very similar, whether resulting from (a) no food, (b) unbalanced diets, (c) mild circulating toxins which interfere with nutrition of cells. In (a) congestion and fatty degeneration were more pronounced, while in (b) more pigment (hemosiderin) was present."

A bibliography is appended.

II. *Cultivation experiments with the blood and spinal fluid of pellagrins*, by E. Francis (pp. 75-80).—Anaerobic cultivation was carried out on the blood of 21 pellagrins and on the spinal fluid of 16 pellagrins. "The results of the examination of the cultures were negative; the cultures either remained sterile or an occasional tube showed a growth which was evidently a contamination."

III. *Further attempts to transmit pellagra to monkeys*, by E. Francis (pp. 81-102).—Attempts to transmit pellagra to laboratory animals (monkeys) by the inoculation of various materials obtained from pellagrins are reported. Of the 94 animals experimented upon only one showed any indications which even suggested pellagra. This exceptional case is described in detail, and the author states that the results of this investigation furnished no support for the view that pellagra is an infectious disease.

The production in dogs of a pathological condition which closely resembles human pellagra, R. H. CHITTENDEN and F. P. UNDERHILL (*Proc. Nat. Acad. Sci.*, 3 (1917), No. 3, pp. 195-197).—By feeding laboratory animals (dogs) upon a diet consisting of boiled dried peas, cracker meal, and cottonseed oil or lard a diseased condition which closely resembled human pellagra was produced. The ingestion of suitable quantities of meat caused these symptoms to disappear.

The intake of a large quantity of peas was found to be less detrimental than smaller amounts. It was more difficult to produce these symptoms in the animals when a diet containing meat, cracker meal, and lard was fed, and for the production of the diseased condition the meat intake had to be reduced to a certain undefined minimum.

The conclusion is drawn that the abnormal condition is due to a deficiency of some essential dietary constituent or constituents.

## ANIMAL PRODUCTION.

Palm kernel cake, C. CROWTHER (*Jour. Bd. Agr. [London]*, 23 (1916), No. 8, pp. 734-749).—This gives a summary of investigations by others at the University of Leeds upon the merits of palm nut kernel cake and meal as a feeding stuff.

On account of the difficulties of mastication and swallowing of palm kernel cake due to its grittiness cattle and sheep did not readily take to this feed. These difficulties were overcome where the palm kernel cake was fed with twice its weight of other cake. In laboratory and farm tests, palm kernel cake compared favorably in keeping quality with most of the oil cakes used on the farm. In digestion experiments with sheep, palm kernel cake gave the following average percentages of digestibility: Total dry matter 74.2, organic matter 75.9, protein 91, fat 97.5, nitrogen-free extract 83.1, and crude fiber 37.1. The

corresponding percentages for palm kernel meal were 75.5, 76.7, 90, 96.4, 86, and 44.8; and for undecorticated Egyptian cottonseed cake 57.7, 58, 74.7, 100 (?), 62, and 84.9. The composition and estimated digestible nutrients of these feeds are given.

In an experiment with five cows a slight increase in the fat content of the milk was produced on feeding palm kernel cake. This increase was more pronounced in the evening milk than in the morning milk, and varied greatly with individual cows. From an examination of samples of the milk fat of two of the cows in this test it was concluded that the feeding of palm kernel cake exercised an effect upon the composition of the milk fat such as might be obtained by the passage of some ingredients of palm kernel oil into the milk fat.

Commercial feeding stuffs, A. J. PATTEN, E. F. BERGER, A. E. SMOLL, and E. A. DE WINDT (*Michigan Sta. Bul. 276 (1916), pp. 3-72*).—In addition to notes on the requirements of the state feeding stuffs law, results are tabulated of the analyses of 1,060 samples of feeding stuffs collected in the State during 1916, including cottonseed meal, cottonseed feed, linseed meal, flaxseed meal, distillers' dried grains, brewers' dried grains, gluten feed, gluten meal, hominy feed, corn feed meal, cracked corn, blood and bone meal, meat meal, meat scrap, digester tankage, granulated bone, beef scrap, alfalfa meal, wheat bran, barley bran, pea bran, wheat, oat, and rye middlings, and mixed and proprietary feeds.

Commercial feeding stuffs, 1915-16, [and] Texas feed law, B. YOUNGBLOOD (*Texas Sta. Bul. 194 (1916), pp. 5-351*).—Analyses are given of cottonseed meal, cottonseed cake, cold pressed cottonseed, cold pressed cottonseed (made from bolly seed), linseed meal, peanut meal, peanut cake, corn feed meal, corn chop, corn bran, hominy feed, milo maize chop, milo maize meal, Kafir corn chop, Kafir corn meal, feterita chop, wheat bran, wheat shorts, barley chop, rolled barley, crushed oats, rice polish, rice bran, cowpea and hull chops, alfalfa meal, dried beet pulp, dried brewers' grains, distillers' grains, fish meal meat scrap, meat meal, digester tankage, bone chop, and various mixed and proprietary feeds, together with other useful data. The text of the law regulating the sale of feeding stuffs in Texas is included.

Sheep husbandry in Oklahoma, W. L. CARLYLE and D. A. SPENCER (*Oklahoma Sta. Bul. 111 (1916), pp. 3-47, figs. 12*).—This bulletin treats in a general way of the sheep industry of Oklahoma, breeds of sheep, management of the farm flock, and common sheep troubles and their treatment, and gives results of a number of feeding experiments with sheep at the station, together with general directions for fattening and marketing sheep.

Notes are given on the progress of an experiment started at the station in 1909 in which an effort is being made to produce a type of sheep suitable for Oklahoma conditions by crossbreeding Dorsets, Shropshires, and Merinos.

The station produced 46 early lambs in the fall of 1913 and sold several of them on the Easter market in Kansas City in the spring of 1914. The total cost of producing the lambs at the farm was \$4.60 per lamb. The freight and commission charges averaged 70 cts. per lamb, making the average total cost per lamb by the time they were placed on the market \$5.30. The receipts per lamb were \$7.

In a feeding experiment during the winter of 1912-13 a lot of six ewes consuming an average of 4.94 lbs. of silage and 0.51 lb. of cottonseed meal per head daily made an average daily gain of 0.39 lb. per ewe for 49 days. During the same period another lot of six ewes on an average daily ration of 2.97 lbs. of alfalfa hay and 0.98 lb. of corn chop made an average daily gain of 0.53 lb. per ewe. No difference could be observed in the health and vigor of the ewes and lambs in the two lots.

In a test in 1914-15, comparing cottonseed meal with alfalfa hay as supplements for cane silage for breeding ewes, a lot of ten ewes fed an average daily ration of 5.85 lbs. of cane silage and 0.5 lb. of cottonseed meal, made an average daily gain of 0.4 lb. per ewe for 105 days. During the same period another lot of ten ewes fed an average daily ration of 4.87 lbs. of cane silage and 1.5 lbs. of alfalfa hay gained 0.16 lb. per ewe daily. The nine ewes that lambled in lot 1 gave birth to 13 lambs, three of which were strong, six of medium vigor, two were weak, and two were born dead. Only eight ewes lambled in lot 2, and from these eight were nine lambs, five of which were strong, two of medium vigor, one weak, and one dead.

A comparison was made of ewes of different breeds and crosses on a maintenance ration of alfalfa hay and corn and Kafir corn silage in 1915-16. The experiment lasted from 79 to 84 days for the different lots. The average daily gain and feed cost per ewe for the different lots were as follows: Lot 1, consisting of nine pure-bred Shropshire and four cross-bred Shropshire-Merino ewes, 0.107 lb. and 1.76 cts.; lot 2, consisting of 17 pure-bred Dorset ewes, 0.19 lb. and 1.91 cts.; lot 3, consisting of eight pure-bred American Merino and five pure-bred Rambouillet ewes, 0.193 lb. and 1.71 cts.; lot 4, consisting of 12 F<sub>1</sub> Shropshire-Dorset ewes, 0.202 lb. and 1.84 cts.; lot 5, consisting of 10 F<sub>1</sub> Merino-Dorset ewes, 0.19 lb. and 1.89 cts.; and lot 6, consisting of 15 ewes that were the offspring of pure-bred rams and cross-bred ewes, 0.16 lb. and 1.65 cts. No conclusions are drawn from this experiment.

In an experiment comparing corn silage with alfalfa hay as roughage for fattening lambs a lot of six pure-bred and cross-bred wether lambs fed an average daily ration of 3.18 lbs. of silage and 2.03 lbs. of a mixture of Kafir corn and cottonseed meal (2:1 by weight) gained 0.42 lb. per head daily for 63 days at a cost of 6.82 cts. per pound of gain. During the same period another lot of six wether lambs of the same breeding, on an average daily ration of 2.88 lbs. of alfalfa hay and 2.03 lbs. of the above grain mixture, gained 0.55 lb. per head daily at a cost of 7.53 cts. per pound of gain. The market finish of both lots was practically the same. In another test beginning October 22, 1913, 30 pure-bred and cross-bred lambs averaging about 92 lbs. per head were divided into two lots of 15 lambs each and fed for 49 days. These lambs had received grain on pasture and were in good condition. Lot 1, on a mixture of Kafir corn silage, alfalfa hay, and corn chop, made an average daily gain of 0.69 lb. per lamb at a cost of 3.96 cts. per pound of gain. Lot 2, fed the same mixture as lot 1 and in addition 0.234 lb. of cottonseed meal per head daily, made an average daily gain of 0.62 lb. per lamb at a cost of 4.24 cts. per pound of gain.

In another test with 20 pure-bred Shropshire lambs, cottonseed meal was compared with alfalfa hay as supplements for cane silage and Kafir corn chop. The ten lambs receiving an average daily ration of 2.95 lbs. of silage, 1.19 lbs. of Kafir corn chop, and 0.49 lb. of cottonseed meal made an average daily gain of 0.35 lb. per head for 84 days at a cost of 7.11 cts. per pound of gain. During the same period, the ten lambs fed 3.02 lbs. of silage, 1.13 lbs. of alfalfa hay, and 1.23 lbs. of Kafir corn chop per head daily, made an average daily gain of 0.46 lb. per lamb at a cost of 5.74 cts. per pound of gain.

Sheep husbandry in the Pacific Northwest, W. HISLOP and C. E. HOWELL (*Washington Sta. Bul.* 134 (1917), pp. 3-24, figs. 12).—This bulletin, which is based upon replies to a circular letter sent to the members of the Washington Wool Growers' Association, gives information as to the actual range practice in the sheep industry in the Pacific Northwest. The answers received represent 201,010 head of ewes, approximately one-half of the sheep population of the State. Of these 85 per cent have a foundation of Merino blood. Of the ewe

flocks 14.3 per cent were Lincolns. Lincoln rams are being used by 44.2 per cent of the breeders reporting, Shropshire rams by 32.6 per cent, Hampshire rams by 23.09 per cent, and Rambouillet rams by 7.6 per cent.

The lambing percentage varied from 70 to 130, the average being 92.32. The weight of the lambs when they reached market varied from 60 to 85 lbs., the average being 73.5 lbs. The weight of fleece of the ewes varied from 7 to 11 lbs., the average being 9.5 lbs. In reference to the annual cost of keeping a ewe, one man who has a band of 2,000 ewes estimated that it cost 75 cts. per ewe. This was the lowest estimate given. The highest was \$5, and the average \$2.59.

Other topics summarized are number of ewes per ram, time of weaning lambs, time and place of marketing lambs, the wool market, causes of death in range sheep, and kind of feed used.

**Experiments in the disposal of irrigated crops through the use of hogs, J. A. HOLDEN** (*U. S. Dept. Agr. Bul. 488 (1917), pp. 25, figs. 3*).—This bulletin reports in detail experiments conducted from 1912 to 1915, inclusive, at the Scottsbluff experiment farm in western Nebraska, for the purpose of obtaining information on the practicability of using alfalfa as hog pasture, the value of different quantities of grain when fed to hogs on alfalfa pasture, the comparative values of corn and ground barley when fed to hogs on alfalfa pasture, and the practicability of hogging down corn. Progress reports of these tests have been noted (*E. S. R.*, 36, p. 170).

Summarizing the whole series of experiments, it is stated that "in three years' experiments, including eight lots of hogs, in which alfalfa pasture was supplemented with a 2 per cent ration of corn, an average gain of 3,181 lbs. per season was made from an acre of alfalfa pasture and 7,844 lbs. of corn. It required an average of 2.47 lbs. of corn in addition to alfalfa pasture to produce 1 lb. of pork. If the gains are valued at 7 cts. a pound and corn at 60 cts. a bushel, or \$1.07 a hundredweight, the average annual return was \$138.75 per acre of alfalfa pasture. If the corn fed is valued at 60 cts. a bushel and the alfalfa pasture at \$15 an acre the average cost of 100 lbs. of gain was \$3.11. If the average yield of the alfalfa plats in the same field is assumed to represent the yield of the pastured plats the hogs paid an equivalent of \$25.13 per ton of hay.

"In two years' experiments with alfalfa pasture, with and without supplemental feed, an average annual return of \$45.08 per acre was secured where no supplement was used, as compared with \$70.20 where a 1 per cent ration of corn was used, \$128.49 from a 2 per cent ration of corn, \$121.96 from a 2 per cent ration of barley, and \$168.25 from a 3 per cent ration of corn. The rate of gain and the carrying capacity of the pasture increased with the quantity of grain fed. Ground barley appeared to be as good, pound for pound, as shelled corn as a feed for hogs on alfalfa pasture.

"Sows and pigs on alfalfa pasture, with a 2 per cent ration of grain, made an average gain of 1,574 lbs. per acre of alfalfa pasture from May 1 to July 1, or a net return of \$66.84 per acre. When corn was used the return varied from \$54.11 to \$69.97 per acre, and when barley was used the return was \$77.76 per acre.

"In three years' experiments, hogging corn without supplementary feed produced an average of 896 lbs. of gain, worth \$65.72 per acre, or \$1.50 per hundredweight of the estimated yield of corn.

"In two years' experiments, hogging corn without supplementary feed produced an average of 744 lbs. of gain, worth \$52.08 per acre, as compared with 930 lbs. of gain, worth \$65.10, where the hogs had access to alfalfa pasture, and 1,029 lbs. of gain, worth \$72.03, where the hogs were fed tankage in addition to the corn. Where no supplementary feed was used the hogs paid \$1.34 per hun-

dredweight for the estimated yield of corn, as compared with \$1.55 per hundred-weight where the hogs had access to alfalfa pasture, and \$1.50 per hundred-weight where tankage was used. The use of either alfalfa or tankage resulted in more rapid and cheaper gains than were secured where no supplementary feed was used."

Fattening swine on rice by-products, H. E. DVORACHEK ET AL. (*Arkansas Sta. Bul. 128 (1916), pp. 24, fig. 1*).—Results are reported of five experiments carried on at the station to determine the relative feeding values of corn, rice polish, and rice bran for fattening swine when fed alone, in various combinations, and when supplemented with various protein supplements. The pigs were fed in pens in the station hog house and had access to dry lots, mineral matter, and water. In the first three experiments the feeds were mixed with water at the time of feeding and fed as a thick slop. In the fourth and fifth experiments the full day's feed was mixed with water in barrels in the evening, one-half of this mixture being fed the next morning and the other half the next evening. The cost of gains was based upon the following prices per hundred-weight for feeds: Corn chop, \$1.50; rice polish, \$1.40; rice bran, \$1.10; wheat shorts, \$1.40; tankage, \$2.50; skim milk, 25 cts.; and buttermilk, 25 cts.

The following table gives the rations fed and some of the results obtained in the five experiments:

*Pig feeding trials.*

Ex-periment No.	Lot No.	Rations fed; weight proportions.	Average daily gain per head.	Feed consumed per pound of gain.	Cost per pound of gain.	Length of experiment.	Average weight per pig at beginning.	Number of pigs per lot.
			<i>Pounds.</i>	<i>Pounds.</i>	<i>Cents.</i>	<i>Days.</i>	<i>Pounds.</i>	
I	1	Corn chop, tankage (9 : 1)...	1.17	4.358	6.97	75	130	6
	2	Rice polish, tankage (9 : 1)...	1.23	3.754	5.67			
	3	Rice bran, tankage (9 : 1)...	1.27	4.488	5.56			
	4	Rice polish, rice bran, tankage (9 : 9 : 2).....	1.16	4.920	6.77			
	5	Corn chop, rice polish, rice bran, tankage (3 : 3 : 3 : 1).....	1.39	4.311	6.25			
	6	Rice polish, rice bran, tankage (6 : 3 : 1).....	1.26	4.018	5.72			
II	1	Corn chop, tankage (9 : 1)...	1.48	3.782	5.96	82	85	5
	2	Rice polish, tankage (9 : 1)...	1.26	3.636	5.49			
	3	Rice bran, tankage (9 : 1)...	1.28	4.478	5.55			
	4	Rice polish, rice bran, tankage (9 : 9 : 2).....	1.16	3.991	5.48			
	5	Corn chop, rice polish, rice bran, tankage (3 : 3 : 3 : 1).....	1.36	4.240	6.15			
	6	Rice polish, rice bran, tankage (3 : 6 : 1).....	1.14	4.286	5.70			
III	1	Rice bran.....	1.10	5.272	5.80	90	110	4
	2	Rice bran, wheat shorts(1 : 1)	1.03	5.794	7.25			
	3	Rice bran, wheat shorts, tankage (6 : 3 : 1).....	1.33	4.700	6.25			
	4	Rice bran, tankage (9 : 1).....	1.13	5.308	6.58			
IV	1	Corn chop.....	1.30	4.754	7.14	63	135	5
	2	Rice bran.....	1.46	4.227	4.65			
	3	Rice polish.....	1.63	3.550	5.01			
	4	Corn chop, rice bran, rice polish (1 : 1 : 1).....	1.72	3.627	4.83			
	5	Rice bran, rice polish (1 : 1).....	1.40	4.044	5.05			
	6	Rice bran, rice polish (2 : 1).....	1.66	3.702	4.44			
	7	Rice bran, rice polish (1 : 2).....	1.49	3.903	5.07			
	8	Rice bran, rice polish (1 : 3).....	1.72	3.550	4.74			
V	1	Corn chop, tankage (9 : 1 to 12 : 1).....	1.21	4.136	6.57	84	75	5
	2	Rice bran, tankage (9 : 1 to 12 : 1).....	1.07	4.612	5.65			
	3	Rice polish, tankage (9 : 1 to 12 : 1).....	1.41	3.420	5.12			
	4	Corn chop, buttermilk.....	1.18	7.003	6.59			
	5	Rice bran, buttermilk.....	1.20	6.867	4.93			
	6	Rice polish, buttermilk.....	1.55	5.299	4.99			
	7	Corn chop, skim milk.....	1.28	8.675	6.64			
	8	Rice bran, skim milk.....	1.26	8.807	5.28			
	9	Rice polish, skim milk.....	1.64	6.749	4.90			

In the tankage lots in experiment 5 the ratio fed was 9:1 during the first six weeks and 12:1 during the last six weeks. "In the lots where skim milk and buttermilk were used a like change in proportions was made."

The authors state that "hogs scour severely when fed large quantities of rice polish when it is dampened just before feeding. The addition of lime water checked the scours. In lots where the rice polish was thoroughly soaked for 12 and 24 hours, no scouring occurred.

"These experiments were all conducted on fairly well grown shotes for fattening purposes, and no indications of incomplete nutrition were noticeable, such as have been reported by some where rice polish was used alone for growing pigs. Rice polish is not as palatable as corn chop, especially during the close of the fattening period. Hogs go off feed readily at that time. When fed with skim milk and buttermilk great gains and an excellent finish are possible."

Detailed data for each lot in the five experiments are tabulated by periods in the appendix.

Breeds of swine, F. G. ASHBROOK (*U. S. Dept. Agr., Farmers' Bul. 765 (1917), pp. 16, figs. 14*).—This gives information concerning the various breeds of swine, their origin, general appearance, development, and adaptability.

How to select a sound horse, H. H. REESE (*U. S. Dept. Agr., Farmers' Bul. 779 (1917), pp. 26, figs. 36*).—This gives concise information on the selection of sound horses by thorough, systematic examination, and points out by means of illustrations how to observe blemishes, vices, faulty conformation, unsoundness, general characteristics, and the indications of age in horses.

A study of the effect of cottonseed meal v. beef scrap upon the egg production, fertility, and vitality of poultry, B. A. ABBENS (*Oklahoma Sta. Bul. 112 (1917), pp. 3-20*).—The first of these experiments with White Leghorns was begun in November, 1914. In this test there were three lots of ten pullets and two cockerels each. These birds were bred at the station from sires and dams of strong constitutional vigor. Each of the lots received a grain ration of Kafir corn and whole wheat, equal parts by weight. In addition, lot 1 received a mash of millrun, corn chop, beef scrap, and bone meal (7:6:2:1); lot 2 a mash of millrun, corn meal, cottonseed meal, and bone meal (6:6:3:1); and lot 3 a mash of millrun, corn chop, cottonseed meal, and bone meal (3:3:9:1). The nutritive ratios of the rations were, for lots 1 and 2, 1:4.5, and for lot 3, 1:3.5. The chicks hatched from the different lots were kept separate from birth and fed on the same type of ration as their parents, due allowance being made for changing the exact composition of the ration to meet the requirements of the growing period. During this test the health of the birds was excellent. One pullet from lot 3 died of roup and one male from the same lot died from the effects of being crop bound.

In a preliminary test of all eggs laid for three weeks before February 2, 1915, the following percentages of fertility were found after seven days incubation: Lot 1, 75.7; lot 2, 97.4; and lot 3, 100. The incubation records from February 2 to July 10, 1915, showed that of 711 eggs set from lot 1, 89.5 per cent were fertile, 32.8 per cent of which hatched; of 535 eggs set from lot 2, 90.8 per cent were fertile, 48.7 per cent of which hatched; and of 334 eggs set from lot 3, 87.7 per cent were fertile, 31 per cent of which hatched. From November 18, 1914, to November 17, 1915, lot 1 produced 1,394 eggs at a profit of \$5.05; lot 2, 998 eggs at a profit of \$1.35; and lot 3, 744 eggs at a profit of 46 cts.

During the season of 1915-16 these birds were rearranged into six lots to eliminate the effect of difference in stock, except that the birds in the original lot 3 were carried along as lot 3 in this test. Lots 1 and 4 were fed the same ration as lot 1 of the former season, lots 2 and 5 the same as lot 2 of the former season, and lots 3 and 6 the same as lot 3 of the former season.

Summarizing incubation records during the season it was found that of 250 eggs set from lot 1, 90 per cent were fertile, 55 per cent of which hatched. The corresponding figures for the other lots were as follows: Lot 2, 230, 90, and 54.1; lot 3, 206, 92.2, and 46.3; lot 4, 262, 88.5, and 56; lot 5, 197, 91.3 and 48.3; and lot 6, 243, 98.5 and 43.9. From November 18, 1915, to May 17, 1916, the hens in lot 1 laid 636 eggs at a profit of \$3.40; lot 2, 552, at a profit of \$2.67; lot 3, 404, at a profit of \$1.63; lot 4, 730, at a profit of \$6.25; and lot 5, 431, at a profit of \$3.63. The egg production record of lot 6 is not given.

The author states that the mortality was much higher in the chicks from the lots fed cottonseed meal, both in the normal and excessive amounts, than in those from the lots fed beef scrap.

Analyses of each of the feeds used are given.

Cost of raising Leghorn pullets, A. G. PHILIPS (*Indiana Sta. Bul.* 196 (1916), pp. 20, figs. 6; *popular ed.*, pp. 8, figs. 4).—The experiments reported in this bulletin covered four seasons' work and involved several thousand White Leghorn chicks. The chicks were reared in 8 by 8 ft. A-shaped colony brooder houses, heated by gasoline, in yards covered with blue grass and clover. After the heat was removed, each brooder house with its chicks was moved to a lot 130 by 150 ft. planted to young fruit trees, the rows of which were intertilled with corn.

The grain ration consisted of sifted cracked corn, sifted cracked wheat, and steel cut oats, equal parts by weight, until the chicks reached a weight of 0.7 lb. each, when the grain was changed to cracked corn and whole wheat. The dry mash consisted of a mixture of bran, shorts, corn meal, and meat scrap (2:2:2:1) to which was added a small quantity of charcoal and ground dry bone. Green feed, grit, and skim milk were fed in abundance. When the cockerels weighed about 1.25 lbs. they were removed to a fattening pen and finished for market.

Detailed data of one of the five experiments are tabulated and compared with the average results of all the experiments.

It was found that the cost of a pullet up to the time of laying varies largely with feed prices. The average gross cost of raising pullets in these tests was 43.4 cts. When the profit from the cockerels was credited, the net cost of the pullets varied from 24.3 to 50.5 cts., the average being 38.1 cts. It took 1.8 eggs to produce a Leghorn chick, the cost of which when hatched was 5.7 cts. To 12 weeks of age the chicks in these tests consumed 5.96 lbs. of feed and 5.07 lbs. of milk per head, or 3.59 lbs. of feed and 3.41 lbs. of milk at a cost of 8.4 cts. per pound of gain. The average weight per pullet in the five experiments at 168 days of age was 2.75 lbs. The percentage of mortality varied from 8 to 29.5 in the different experiments, the average being 17. In these experiments 100 pullets were raised from every 457 eggs set.

Plans are given of the Purdue shed-roofed colony brooder house.

Temperature experiments in incubation, A. G. PHILIPS (*Indiana Sta. Bul.* 195 (1916), pp. 31, figs. 5; *popular ed.*, pp. 8, figs. 5).—These experiments were planned for the purpose of determining the influence of different temperatures in the incubator on brown and white eggs, the upper and lower temperature limits of artificial incubation, and the influence on temperature readings of placing thermometers at different heights in the machine.

Four 150-egg incubators were used. They were of the hot-air type, supplying heat by both radiation and diffusion, and moisture by a sand tray underneath the egg trays. The five thermometers used were standard incubator thermometers, generally known as hanging, standing, touching, and Inovo. The hanging thermometer was suspended from the top of the incubator, 2 in. above the center of the egg tray. The standing thermometer was on a metal stand in the center,

toward the front of the machine, the bulb on a level with the top of the eggs but not touching them. The touching thermometers were two in number, one on brown and one on white eggs, near the standing thermometer. The bulbs of these were on a level with the top of the eggs and touching them. The Inovo thermometer, which is supposed to register the temperature of the germ in an egg, was placed near the other thermometers.

Four experiments were made with each incubator, one in 1913, one in 1915, and two in 1916. Brown and white eggs from White Plymouth Rock and White Leghorn pullets, respectively, were used. Except in the first experiments the eggs were so selected as to eliminate all possible influences on the hatch by some particular hen or because of the age of the eggs. The machines were run at the following temperatures as registered by the standing thermometer during the first, second, and third weeks: Machine No. 1, 100, 101, 102° F.; machine No. 2, 101, 102, 103°; machine No. 3, 102, 103, 104°; and machine No. 4, 103, 104, 105°. The following table gives some of the results obtained:

*Results of incubation experiments with white and brown eggs.*

Machine No.	Eggs set.		Eggs infertile.		Dead germs.		Chicks dead in shell.		Chicks hatched.	
	White.	Brown.	White.	Brown.	White.	Brown.	White.	Brown.	White.	Brown.
1.....	225	225	16	26	9	17	36	56	164	126
2.....	295	300	23	37	27	38	37	59	208	166
3.....	206	300	22	40	8	31	70	70	196	151
4.....	296	300	27	34	25	50	131	135	113	89

No reason from the standpoint of incubation was found for the poor showing of the brown eggs as compared with the white eggs. It was found brown and white eggs need the same temperature. Machine No. 1 produced 69.3 per cent of vigorous chicks to fertile eggs; machine No. 2, 69.5 per cent; machine No. 3, 64.4 per cent; and machine No. 4, 30.5 per cent. In every test machine No. 2 produced the largest, plumpest, and best chicks. The chicks in machines Nos. 1 and 3 were very similar, but those in No. 4 were poor and weak in every hatch.

The average weekly temperatures for the four experiments as recorded by the different thermometers in incubator No. 2, with which the best hatches were obtained, were as follows:

*Average temperatures in machine No. 2.*

Period.	Kinds of thermometers.				
	Standing.	Touching on white eggs.	Touching on brown eggs.	Hanging.	Inovo.
First week.....	°F. 100.9	°F. 101.5	°F. 100.9	°F. 104.7	°F. 98.0
Second week.....	102.1	102.6	102.4	104.9	99.8
Third week.....	103.0	103.7	103.4	104.3	101.2
Average.....	102.0	102.6	102.2	104.6	99.7

It is stated that the incubator records show that the temperatures were held practically to the desired point daily.

With the type of incubator used in these experiments it was found that "if a touching thermometer is used it should be  $0.5^{\circ}$  higher than a standing, regardless of color of eggs. If a hanging thermometer is used it should be run on an average of  $2^{\circ}$  higher than a standing, with a greater difference the first week and a less difference the third week. The Inovo should be run about  $2.2^{\circ}$  lower than a standing."

In a minor experiment in connection with one of the main experiments it was found that "a temperature with a standing thermometer of  $100.5^{\circ}$  the first week,  $101.5^{\circ}$  the second, and  $102.5^{\circ}$  the third week compares well in temperature and hatching results with a hanging thermometer temperature of  $103^{\circ}$  for three weeks."

In an experiment run in duplicate in 1911 with two of the experimental incubators and using white eggs, machine No. 1 was controlled by a standing thermometer and run at  $101$ ,  $102$ , and  $103^{\circ}$ , respectively, for the three weeks, and machine No. 2 by the Inovo thermometer and run at  $100.5^{\circ}$  for the three weeks. The average hatching record of machine No. 1 was as follows: Eggs set,  $147.5$ ; infertile eggs,  $9.5$ ; dead germs,  $8.5$ ; dead in shell,  $27.5$ ; and chicks hatched,  $102$ . For machine No. 2 the corresponding averages were  $149$ ,  $12$ ,  $7.5$ ,  $25.5$ , and  $104$ . In this experiment incubator No. 1 was kept reasonably near the desired temperatures by the standing thermometer, the average for the three weeks being  $102.2^{\circ}$ . At the same time the Inovo thermometer in this machine registered  $98.3^{\circ}$  the first week,  $99.6^{\circ}$  the second, and  $101.1^{\circ}$  the third, averaging for the whole period  $99.6^{\circ}$ . In incubator No. 2, controlled by the Inovo thermometer, the temperature registered  $100.4^{\circ}$  the first week,  $100.6^{\circ}$  the second week, and  $100.6^{\circ}$  the third week, averaging for the whole period  $100.5^{\circ}$ . The standing thermometer in this machine registered  $103^{\circ}$  the first week,  $102.7^{\circ}$  the second week, and  $102.3^{\circ}$  the third week. In this test the standing thermometer temperatures of the two machines varied only  $0.5^{\circ}$ , but one increased during the hatching period and the other decreased, yet the hatches were similar. The results of this experiment tend to show that  $100.5^{\circ}$  is not the only temperature desirable with an Inovo thermometer.

The data in connection with these experiments are tabulated and discussed in detail.

Goose raising, H. M. LAMON and A. R. LEE (*U. S. Dept. Agr., Farmers' Bul. 767 (1917), pp. 16, figs. 8*).—Information is given in reference to the appearance and adaptability of the different breeds of geese, together with details as to breeding, feeding, and marketing.

### DAIRY FARMING—DAIRYING.

Report of the dairy husbandry department, O. F. HUNZIKER (*Indiana Sta. Rpt. 1916, pp. 29-40*).—In testing rations for milch cows three lots of 5 cows each were fed six rations for 150 days. All the rations contained ground corn and corn silage, and in addition ration 1 contained cottonseed meal and alfalfa hay, ration 2 cottonseed meal and soy-bean hay, ration 3 linseed meal and alfalfa hay, ration 4 linseed meal and soy-bean hay, ration 5 gluten feed and alfalfa hay, and ration 6 gluten feed and soy-bean hay.

It was found that "a ration used in milk production, which contains ground corn, corn silage, and a leguminous hay requires but a limited amount of protein-carrying concentrates in order that it may be properly balanced. The three protein-carrying concentrates used in this experiment affected the cost of the rations less than any other of the four feeds of which the ration was composed. When fed in connection with alfalfa hay, cottonseed meal was the most economical source of protein, gluten feed ranking second and linseed meal

standing third. . . . Alfalfa hay was 12 per cent more economical as a milk-producing roughage than soy-bean hay when both were selling at the same price per ton. This does not take into account the greater quantity of soy-bean hay refused, due to its unpalatable characteristic.

"The cost of milk was affected to the greatest degree by varying the price of corn; the hay was of next importance, the corn silage ranked third, and the protein-carrying concentrates fourth. The hay and corn exerted almost the same influence upon the cost of milk. The use of soy-bean hay caused an increase in body weight and a decrease in daily milk and butter-fat production.

"Properly balanced rations are, approximately, equally efficient in the production of milk and butter fat per unit consumption of dry matter. The nutritive ratio of a ration may be varied within reasonable limits without materially affecting the productive power of the ration."

In the experiment to determine the effect of cottonseed meal and linseed meal upon the breeding power of dairy heifers (E. S. R., 34, p. 775), 16 heifers fed in winter a ration of wheat bran, corn silage, and alfalfa hay supplemented with 3.103 lbs. of cottonseed meal daily were bred an average of 1.06 times each, the average age at time of conception being 1 year, 7 months, and 6 days. Nineteen heifers fed the same as the above lot, except that 3.055 lbs. of linseed meal replaced the cottonseed meal, were bred an average of 1.8 times each, the average age at conception being 1 year, 7 months, and 26 days.

In experiments upon the pasteurization of cream for butter making it was found that in the case of sour, gathered cream that is not neutralized pasteurization at 145° F. for 20 minutes is the most satisfactory process from the standpoint of germ-killing efficiency and quality of butter.

In studies upon the changes occurring in butter and milk fat during storage it was found that the proteins are gradually hydrolyzed into simpler compounds. During this hydrolysis, amino acids are formed as one of the decomposition products. The degree of hydrolysis depends upon the initial condition of the proteids, the quantity of hydrolyzing agents present, and the temperature at which the butter is kept. The percentage of gain in proteid nitrogen not precipitated by phosphotungstic acid was 4.157 for raw cream butter, 3.465 for butter from cream pasteurized at 145° for 20 minutes, 3.161 for butter from cream pasteurized at 165° flash, and 2.99 for butter from cream pasteurized at 185° flash. Little variation was found in the constants of the fat of stored butter with the exception of the acid value, which showed a marked increase in the raw cream butter and smaller increases in butters from cream pasteurized at different temperatures.

Bacteriological analyses made of the cream and butter in connection with the pasteurization experiment show that pasteurization at 145°, holding process, "gives the greatest killing efficiency for all varieties of micro-organisms present. The flash system at 185° gives next best killing efficiency but does not give uniform results. The flash system at 165° shows lowest killing efficiency for all varieties of micro-organisms and is the most variable of the three methods."

Preliminary studies upon the cause of oily flavor in butter from cream pasteurized at 185° indicate that this condition is due to a combination of the high degree of heat in the presence of high acidity.

Notes are given on the activities of the department in the testing of purebred dairy cows and creamery inspection work.

Feeding and management of dairy calves and young dairy stock, W. K. BRAINERD and H. P. DAVIS (*U. S. Dept. Agr., Farmers' Bul. 777 (1917), pp. 19, figs. 5*).—In addition to a detailed discussion of this subject, brief information is given on calf diseases.

**Milking machines: A study of the practical operation of 108 milking machines in Jefferson County, New York, F. E. ROBERTSON and C. W. GILBERT** (*Jefferson Co. [N. Y.], Farm Bur. Bul. 7 (1916), pp. 12*).—A brief report is given of a study of the operation of 108 milking machines representing seven different makes in Jefferson County, N. Y. The study was conducted during very hot weather in July and August, 1916. In order to compare hand milking with machine milking information was also accumulated from 51 different milkers, including men, women, and boys relating to the time required to milk out 100 lbs. of milk by hand.

It was found that with the different makes of milking machines it required from 80 to 126.5 minutes to milk 100 lbs. of milk per unit, as compared to 68 minutes by hand. Under the same conditions the different units milked from 6 to 7.5 cows per hour as compared to 6.9 cows per hour by hand. These data include the customary time required to start the engine, place the teat cups on the cows, change the units from cow to cow, and care for the milk in the usual manner. The strippings after milking with a mechanical milker averaged less than 1 lb. per cow.

The most efficient combination of operators and units seemed to be where one operator used four single units or two double units, although greater speed was made with other combinations. One operator using three single units obtained 100 lbs. of milk in 28.8 minutes, while one operator using two double units obtained 100 lbs. of milk in 32.4 minutes.

It took from 15 to 20 minutes daily on the average to properly cleanse the milking machines.

**Market milk contests and dairy surveys, L. H. COOLEIDGE** (*Michigan Sta. Rpt. 1916, pp. 251-255*).—Results are given of a number of market milk contests, market cream contests, and sanitary surveys of milk plants, dairy farms, and milk plant water supplies made in a number of places in the State during the year for the purpose of establishing a proper basis for educational and extension efforts in connection with milk production and marketing.

A sanitary survey of the milk plants and farms supplying milk for the city of Flint, Mich., showed an average score of 58.3 for the milk plants, none of them scoring above 75. The average score of 40 dairy farms was 59.4, only one of which scored above 75. In connection with this survey a milk contest was held in which the milk samples were taken from wagons without previous warning. Of the 18 samples examined only one scored above 90 and nine below 60. During the following March a second milk contest was held at Flint, in which 31 per cent of the samples scored above 90 and none below 60. This contest included samples prepared for the contest and samples taken from wagons without warning.

Bacteriological analyses of water made in connection with these dairy surveys showed that 37 per cent of the city water samples and 70 per cent of the samples of rural dairy water supplies examined were sewage polluted.

**A plea for uniformity in municipal milk regulations, L. P. BROWN** (*Milk Dealer, 6 (1917), No. 4, pp. 24, 26, 28, 30-32, 34*).—In this paper, which was read before the International Association of Dairy and Milk Inspectors at Springfield, Mass., the author compares the milk regulations of 17 of the larger cities of the United States, and shows by means of tables the lack of uniformity in the requirements of the various cities for the production of sanitary milk.

**Report of the committee on methods of appointment of dairy and milk inspectors and their compensation, E. KELLEY** (*Milk Dealer, 6 (1917), No. 4, pp. 18-20, fig. 1*).—In this report, read before the International Association of Dairy and Milk Inspectors at Springfield, Mass., tabulated data with brief com-

ments are given of information received from 31 States and 102 cities concerning methods of appointment and compensation of dairy and milk inspectors.

**Reliability of the bacteriological analysis of milk, H. W. CONN** (*Milk Dealer*, 6 (1917), No. 4, pp. 50-56).—In this paper, read before the International Association of Dairy and Milk Inspectors at Springfield, Mass., the author discusses the reliability and significance of bacteriological milk analysis. A summary is given of an extensive series of tests made during the last three years in a considerable number of laboratories to determine the amount of variation in the analysis of milk that may be introduced by conditions beyond control.

The results of 20,000 analyses show that by standard methods used in routine laboratories by ordinary laboratory assistants variations of from 25 to 30 per cent in the analysis of identical samples of milk may be expected to occur. Where special care is taken by experts a much closer result is obtained. However, in view of the enormous range in number of bacteria occurring in different samples of milk this amount of variation in the results of bacterial counts is considered of no real significance. "A bacteriological analysis of milk can not be relied upon to give actual numbers of bacteria, but only approximate numbers. . . .

"The bacteriological analysis of milk is not to be taken as indicating in itself either a condition of safety or a condition of danger, but only as a warning. Good, clean, fresh milk will have a low bacterial count, and a high bacterial count means dirt, age, disease, or temperature. A high bacterial count is therefore a danger signal, and justifies the health officer in putting a source of supply with a persistently high bacterial count among the class of unwholesome milk.

"Bacteriological analysis offers the only means of grading milk according to its sanitary character. A grading system applied to the milk industry is the great desideratum for the improvement of the industry in the future from the standpoint of the producer, the dealer, and the consumer."

**Why cream tests vary and how to produce first-grade cream, E. O. CHALLIS** (*Union So. Africa Dept. Agr. [Pub.]*, 82 (1915), pp. 21, figs. 9).—The author explains the various points connected with the successful operation of cream separators and reports the results of several series of tests with a 45-gal. separator to ascertain the cause of variations in cream tests.

In testing the effect of variations in the speed of separators, using milk testing 4.3 per cent fat and separating at a temperature of 86° F., it was found that turning the handle 60 revolutions per minute, the prescribed speed, gave cream testing 54 per cent fat and turning at 55, 50, and 45 revolutions per minute, gave creams testing 46, 31, and 26 per cent, respectively. Irregular turning produced cream testing 44 per cent fat. In separating milk testing 3.5 per cent fat at 86 to 90° when the separator handle was turned at 60 revolutions per minute, cream containing 34 per cent fat was obtained, and when turned at 74 and 40 revolutions per minute 52 and 20 per cent creams, respectively, were obtained. Turning the handle irregularly produced 27 per cent cream.

In a test in which milks of different fat contents were separated under identical conditions, the separator being turned at 60 revolutions per minute and the milk separated at 88°, milk testing 4.8 per cent fat produced 49 per cent cream, and milk testing 2.9 per cent produced 38 per cent cream.

The final experiment had to do with the effect of temperature of the milk upon the fat content of the resulting cream. Using 3.7 per cent milk and turning the separator at 60 revolutions per minute, milk separated at 90° produced 42 per cent cream, and milk separated at 80 and at 74° produced 51 and 52 per cent creams, respectively.

Notes are given on the care of cream on the farm.

**Marketing creamery butter**, R. C. POTTS and H. F. MEYER (*U. S. Dept. Agr. Bul. 456 (1917), pp. 37, figs. 17*).—General information is given regarding the packing, shipping, and marketing of creamery butter, based on a general survey in over 50 cities. The more complex economic phases of butter marketing are not discussed.

The authors state that "a knowledge of the various market requirements, marketing methods, and marketing facilities is essential for the successful marketing of creamery butter. Particular attention should be given to the market requirements as regards quality of butter and size and style of packages. Critical markets require a clean-flavored, firm-bodied, well-made piece of butter for which they pay the highest prices. Butter of inferior quality is discriminated against by critical buyers and usually sells at prices considerably below the better grades.

"The use of neat and attractive containers, standardized to a uniform size and style, is highly desirable both for local and foreign markets. Carelessly packed butter has not only a poor appearance but also usually brings a lower price. The branding of bulk-butter packages (tubs and cubes) with the gross, tare, net weight, and churning number greatly facilitates the handling and inspection of butter in the market. The use of consumers' packages for butter is increasing. A standardization of these, particularly the cartons, is especially desirable.

"Market grades for butter have been established by a number of wholesale produce organizations. While these conform quite closely to a uniform standard it is generally conceded that butter which will pass in some markets for a certain grade may be classed differently in another, owing to a different standard of quality which the butter inspector may use. The employment of butter inspectors and the maintenance of market inspection is at present provided in the wholesale markets by the organizations of wholesale butter distributors."

Statistics of cold-storage holdings of butter in 1914 indicate that 81 per cent of the butter stored is delivered into storage during May, June, July, and August. The deliveries out of storage are more gradual. The average length of storage is approximately 6.2 months. "The cost of financing and handling butter in storage is approximately one-fourth cent per pound per month.

"Regular, scheduled refrigerator rail service is provided for butter in the more highly developed dairy sections. Express service often is employed for shipping to near-by markets and may be used in combinations with refrigerator freight service in reaching the more distant markets. Cooperation among creameries has proved of value in obtaining and using refrigerator service where creameries are located in close proximity to each other.

"State brands for butter which creameries are permitted to use when they have complied with State requirements have been adopted by Minnesota, Iowa, and Michigan. They are intended to convey a guaranty of purity and quality in the butter which will be of mutual benefit to both the producer and the consumer. The establishment of brands is essential for effective advertising or in retaining the identity of the manufacturer of a product. Appropriate advertising and salesmanship are also two vital factors in successful market distribution. In marketing a branded product it is highly important that a sanitary and attractive package be used and that a certain standard of quality be maintained."

### VETERINARY MEDICINE.

**Report of the veterinary department**, R. A. CRAIG (*Indiana Sta. Rpt. 1916, pp. 67, 68*).—The incubation for two weeks of filtrates obtained by passing hog-cholera blood through Pasteur-Chamberland and Berkefeld filters resulted

in a slight cloudiness and a very noticeable precipitate. Microscopic examinations of the filtrates showed an increase in the so-called granules. An increase in the albumin content of the filtrates during the incubation period was also observed. Examination of the filtrate after the removal of this albumin did not show the presence of the granules.

Five pigs which were removed from their mothers at birth and fed by hand were injected intravenously and intraperitoneally with 60 cc. of a hog-cholera blood filtrate. Three similar animals were used for controls. After four days both the inoculated and control pigs were bled and the blood examined microscopically. No difference was observed between the blood of the two sets of animals. The inoculated pigs on post-mortem examination showed slight hemorrhages in the lungs, lymphatic glands, and kidneys. The control pigs showed hemorrhagic foci in the kidneys, a condition which has been shown to be common in young pigs.

An attempt to attenuate hog-cholera blood by passage through rabbits and using a virus prepared by extracting the carcasses of injected rabbits with physiological salt solution and passing it through a Pasteur filter was unsuccessful. Six of the eight pigs inoculated with this virus died of acute hog cholera and five exposure check pigs also died.

Hog-cholera blood dried over sulphuric acid for periods varying from 10 to 15 days and subjected to heat of from 40 to 42° C. for periods of from four to seven days did not produce the disease. No immunity, however, was conferred, as the inoculated pigs died later when exposed to hog cholera. The work to determine the relative virulence of hog-cholera blood at different periods of the disease, as previously noted (E. S. R., 34, p. 783), was continued. The data are reported in tabular form.

Of 156 samples of blood tested for infectious abortion in cattle by the agglutination test, 96 yielded negative results and 60 positive reactions.

**Report of the veterinary department for the biennial period, July 1, 1912, to June 30, 1914, J. I. GIBSON** (*Bien. Rpt. Vet. Surg. Iowa, 9 (1913-14), pp. 36*).—This report includes data relating to hog cholera control work in Dallas County, Iowa, and rules and regulations adopted by the animal-health commission of the State.

**Fifteenth report of the Live Stock Sanitary Board and chief veterinary inspector of Maryland, 1914-15, L. HICKMAN ET AL.** ([*Bien.*] *Rpt. Live Stock Sanit. Bd. and Chief Vet. Insp. Md., 15 (1914-15), pp. 45, figs. 7*).—This report deals with the occurrence of and control work with infectious diseases of animals in Maryland, reporting at length on the occurrence of and eradication work with foot-and-mouth disease during the recent outbreak.

**Proceedings of the fifteenth annual convention of the North Dakota Veterinary Association** (*Proc. N. Dak. Vet. Assoc., 15 (1916), pp. 46*).—The greater part of this report is taken up by a paper on Sterility in Cattle, by W. L. Williams (pp. 15-39).

**Annual report of the veterinary service for the year 1915, W. LITTLEWOOD** (*Ann. Rpt. Vet. Serv. Egypt, 1915, pp. VI+59; abs. in Trop. Vet. Bul., 4 (1916), No. 4, pp. 192-196*).—The several sections of this, the usual annual report (E. S. R., 36, p. 180), deal with contagious diseases, the work of the veterinary pathological laboratory, and the work of the school of veterinary medicine.

A Note on Spraying of Cattle with Special Dips for the Eradication of Ticks, by H. Cooper (pp. 45-48); a census of cattle, buffaloes, sheep, goats, camels, pigs, horses, mules, donkeys, etc., in Egypt during 1914 as compared with that of 1915; and the return of animals slaughtered in the principal abattoirs during the year are appended.

Directions for preparation of veterinary specimens for examination, M. FRANCIS (*Texas Sta. Circ. 16 (1916), pp. 7, figs. 3*).—A brief descriptive account.

Studies on the blood proteins.—I, The serum globulins in bacterial infection and immunity, S. H. HURWITZ and K. F. MEYER (*Jour. Expt. Med., 24 (1916), No. 5, pp. 515-546, figs. 7*).—The results of the investigation reported are summarized as follows:

"The progress of an infection is usually associated with marked changes in the serum proteins. There may be an increase in the percentage of the total protein during some stage of the infection, and there is usually a change in the albumin-globulin ratio with an increase in the total globulins. This rise may antedate the development of any resistance by a considerable period of time. The nonprotein constituents of the blood show fluctuations with a tendency to rise as the infection progresses.

"The process of immunization is in almost all instances associated with a definite increase in the globulins of the blood, and in some cases with a complete inversion of the normal albumin-globulin ratio. This may be produced both by living and dead organisms and by bacterial endotoxins. Massive doses usually result in an upset which shows no tendency to right itself during the period of observation. A rise in the globulins has been shown to occur long before the animal develops immune bodies in any appreciable concentration; and where the globulin curve and antibody curve appear to parallel one another it can be shown by a careful analysis of both curves that there is a definite lack of correspondence at various periods of the experiment. Animals possessing a basic immunity show a more rapid rise in the globulin curve following inoculation."

No parallelism was observed between the leucocytic reaction and the globulin reaction. The globulins may be as high during periods of leucopenia as during the period of a leucocytosis. As striking an increase in the serum globulins is produced by bacterial endotoxins as is produced by living and killed bacteria. This would seem to indicate that a bacterial invasion of the organism is not absolutely essential for the globulin changes, and that the toxogenic factor in infection and immunity must play a part in the production of the changes noted.

"Inflammatory irritants injected intraperitoneally also result in a globulin increase. In this case the changes produced may best be explained by the toxogenic effect produced by the protein-split products resulting from the inflammatory condition. Intraperitoneal injections of killed bacteria give rise to a more rapid increase in the serum globulins. The rapidity of the response following intraperitoneal as compared with intravenous injections doubtless stands in intimate relationship to the neutralizing power possessed by the blood serum, and perhaps to the more extensive surface of absorption following injection by the intraperitoneal route."

Experimental observations on the pathogenesis of gall-bladder infections in typhoid, cholera, and dysentery, H. J. NICHOLS (*Jour. Expt. Med., 24 (1916), No. 5, pp. 497-514*).—The results of investigations with the common duct fistula method in the rabbit lend support to the theory of the production of gall-bladder lesions in typhoid by a descending infection of the bile from the liver. "More bacilli appear in the bile with increased doses, and more gall-bladder infections are obtained by increased doses. More bacilli appear in the bile after mesenteric vein injection than after ear vein injection, and more lesions result under the first condition. More bacilli appear in the bile after injection of the same dose in immunized animals than in normal animals, and more lesions also result in immunized animals."

The fate of the micro-organisms after their appearance in the bile seems to be largely determined by the antiseptic properties of the bile which are largely due to its alkalinity. It appears possible to protect the rabbit against gall-bladder infections, at least to some degree, by the previous injection of sodium bicarbonate.

Alkaline therapy is suggested in the prevention and cure of gall-bladder carriers.

A comparison of the "defibrination" and "oxalate" methods of serum preparation as applied to hemorrhagic septicemia and anthrax sera together with some analyses of buffalo and hill bull blood, R. V. NORRIS (*Agr. Research Inst. Pusa Bul. 60 (1916), pp. 15*).—The results of the investigation submitted in detailed tabular form show that the oxalate method gives a considerably increased yield of serum as compared with the defibrination method in the preparation of hemorrhagic septicemia and anthrax sera. Serum prepared by the oxalate method is also greatly superior in appearance to that obtained by defibrination and centrifugalization. In the case of buffalo blood the oxalate procedure saves considerable centrifugalizing, which is of practical importance in the preparation of large quantities of sera. With hill bull blood the corpuscles do not settle, and the blood must be centrifugalized. A series of bleedings taken at short intervals was found to increase the yield of serum progressively, the third bleeding giving the largest percentage of serum. Analyses of normal buffalo and hill bull blood indicated that the chief point of difference was the considerably larger percentage of globulins in the serum from the hill bull blood.

Anthrax or charbon, H. J. WASHBURN (*U. S. Dept. Agr., Farmers' Bul. 784 (1917), pp. 16*).—This supersedes Farmers' Bulletin 439, previously noted (*E. S. R., 25, p. 381*).

The diagnosis of tuberculosis by means of tuberculin with special reference to the intrapalpebral method, N. MORT (*Atti R. Isl. Incoragg. Napoli, 6. ser., 67 (1915), pp. 71-89*).—This material has been previously noted from another source (*E. S. R., 36, p. 578*).

Experiments on cattle plague, C. TODD and R. G. WHITE (*Cairo, Egypt: Govt., 1914, pp. IX+133, figs. 136*).—This is a report of work carried out for the commission nominated by the Council of Ministers April 13, 1912.

The several parts of the report deal with the localization, etc., of rinderpest virus in the animal body, methods of the transmission of the disease and tenacity of virus outside the body, general considerations on the nature of the causal organism, a bibliography on the subject, meteorological data, and details of the experiments. An appendix includes a brief abstract of the results obtained.

Hog cholera, M. E. TABUSSO (*Bol. Min. Fomento [Peru], 14 (1916), No. 4, pp. 5-23*).—This is a general discussion with special reference to observations of the disease in Peru. The topics considered are spread of the disease, etiology, clinical forms, diagnosis, therapy, and prophylaxis.

Tuberculosis of hogs, J. R. MOHLER and H. J. WASHBURN (*U. S. Dept. Agr., Farmers' Bul. 781 (1917), pp. 19, figs. 4*).—This is a revision of the circular previously noted (*E. S. R., 27, p. 684*). The topics discussed are the prevalence and economic importance of the disease, methods of infection, symptoms of tuberculosis in hogs, the tuberculin tests, lesions, and preventive measures.

Osseous cachexia and verminous cachexia of equines.—Cylicostomiasis, C. CONREUR (*Bul. Soc. Path. Exot., 9 (1916), No. 8, pp. 600-633; abs. in Trop. Vet. Bul., 4 (1916), No. 4, pp. 181-184*).—This is a discussion of a disease of horses, mules, and asses occurring in Brazil, known as "cara inchada" or

"bighead," which is apparently the disease known elsewhere as osteoporosis or osteomalacia. In a number of cases examined post-mortem the author always found innumerable small worms of the genus *Cylicostomum*, in addition to others. Considering the disease to be of verminous origin he has applied the name *cylicostomiasis*.

**Pseudo-epizootic encephalomyelitis of the horse, G. URBAIN** (*Bul. Soc. Path. Exot.*, 9 (1916), No. 8, pp. 557-561; *abs. in Trop. Vet. Bul.*, 4 (1916), No. 4, pp. 184, 185).—This article relates to a highly fatal disease of equines in Parana, Brazil, known as "peste de cegar" (blindness disease), which is characterized by the following symptoms: Blindness; circular movements followed by a unilateral paralysis; immobility, the animal remaining for hours without moving; and a stage of excitability, depression, coma, and death. The affection is said to differ from Borna disease. The author is of the opinion that it is caused by a fungus of the genus *Aspergillus* found in corn.

Further investigations of the etiology and control of infectious abortion in mares, E. S. GOOD and W. V. SMITH (*Kentucky Sta. Bul.* 204 (1916), pp. 337-396, pls. 8).—This bulletin gives a brief historical review of other investigations; compares the disease of infectious abortion in the mare and cow; gives a history of the studs and cases investigated; and takes up the morphological, cultural, and physiological characteristics of *Bacillus abortivo-equinus*; agglutination and complement-fixation tests; agglutination and complement-fixation tests to determine the relationship, if any, of *B. abortivo-equinus* and other organisms belonging to subgroup II of the colon-typhoid group; inoculation experiments; production of a hyperimmune serum for infectious abortion in mares; experiments in immunizing animals with a bacterin made from *B. abortivo-equinus*; and the effect of methylene blue, hexamethylenamin, carbolic acid, and potassium permanganate on *B. abortivo-equinus*.

The authors have isolated *B. abortivo-equinus* from nine different studs of aborting mares and one stud of aborting jennets. By cultural, agglutination, and complement-fixation tests the organism has been found to be distinct from the other pathogenic organisms of subgroup II of the colon-typhoid type. The organism varies in its physiological property of splitting lactose and saccharose, as previously noted (E. S. R., 35, p. 785). A 0.1 per cent solution of potassium permanganate was found to destroy the organism in one minute, and a 1 per cent solution of carbolic acid in the same time. A 1:1,000 solution of methylene blue destroyed the organism in five minutes, while a saturated solution of boric acid required three hours for the destruction of the germ. It is indicated that all of these solutions, in the strengths mentioned, can be used as douches and not injure the mare.

Subcutaneous injections of *B. abortivo-equinus* produced abortions in guinea pigs and rabbits, and an intravenous injection of this organism produced abortion in the hog and sheep. The feeding of large amounts of the germ to a pregnant sow, however, produced no injury. The feeding of the organism to pregnant ewes did not produce abortion. Small doses injected intravenously into hogs resulted only in lassitude, while a large dose given intravenously and repeated produced death. The organism could be recovered from the internal organs of the animal. The intravenous injection of 1 cc. of a physiological salt suspension of *B. abortivo-equinus* into a pregnant mare produced abortion in 12 days in one case, and the injection of 2 cc. of a similar suspension into another pregnant mare produced abortion in 10 days.

A suspension of the organism in sterile water mixed with ship stuff and fed to a pregnant mare produced a persistent diarrhea which would not yield to medical treatment and resulted in the death of the animal 20 days after receiving the dose. The organism was recovered from the heart blood of the mare

and the liver of the fetus, thus "demonstrating to our satisfaction that the organism had passed through the intestinal walls to the blood stream of the mare and fetus, and would have produced abortion had the mare lived."

A bacterin prepared by suspending the organism which had been grown on plain agar in physiological salt solution and heated to 60° C. for two hours protected rabbits against 10 times the lethal dose of the organism. The subcutaneous injection of rather large doses of the bacterin in pregnant mares produced no bad effects other than an occasional abscess at the site of inoculation. The animals so treated delivered live healthy colts. The injection of increasing doses of bacterin followed later by the subcutaneous injection of increasing doses of the live organism caused a pregnant mare to deliver a live, although weak, colt which soon developed into a strong animal. The drastic treatment had a depressing effect on the mare, but she later recovered and four months afterwards was in excellent condition.

The results obtained with the hyperimmune serum have been previously noted (E. S. R., 35, p. 80).

It is indicated that, "in the light of our present investigations, a bacterin made of the *B. abortivo-equinus* injected subcutaneously will, if given to a pregnant mare in proper and increasing doses, do no harm and will, in all probability, immunize her against the disease of infectious abortion if the bacterin be administered before the disease is contracted in a natural manner. In the production of this bacterin we grow the *B. abortivo-equinus* on agar slants. The culture is then washed three times with normal salt solution in a centrifuge."

See also previous notes (E. S. R., 29, p. 779; 35, p. 885).

The avenue and development of tissue-infection in intestinal trichomoniasis, P. B. HADLEY (*Rhode Island Sta. Bul. 168 (1916), pp. 3-64, pls. 11, figs. 2*).—In continuation of the studies previously noted (E. S. R., 36, p. 483), the author reports upon the manner in which the flagellates responsible for intestinal trichomoniasis penetrate the cecal epithelium and enter the subepithelial tissues, there to produce characteristic lesions, and describes the course of the infective process.

"As a result of a more or less fluid condition of the cecal content the flagellates multiply in vast numbers by autogamous reproduction and finally migrate into the crypts of Lieberkühn, where they tend to gather at the terminal branches and produce a marked bulging of the fundi.

"Either through pressure or natural invasive power, or both, the free motile flagellates (trophozoites) penetrate the goblet cells, force out the nucleus, or push it to one side, break through the base of the cell, subsequently through the basement membrane, and enter the connective tissue of the mucosa. A large number of flagellates may penetrate the same rift in the epithelial wall and subsequently become disseminated.

"With the further passage of flagellates through the epithelial wall they tend at first so to congregate as to separate the epithelial wall of the fundus from the basement membrane and from the core of the villus. The first mechanical effect upon the epithelial cells of the fundus is the production of a ragged, fringed appearance at the basement end.

"Either as a result of the mechanical damage brought about by the earliest of the invading flagellates or due to the effect of toxic metabolic products, the epithelial cells at the fundus of the crypts become further disorganized, permit other flagellates to pass, probably through intercellular rifts, and finally degenerate, leaving at the site of the fundus only free nuclei, cellular debris, and flagellates. Sometimes the epithelium of the fundus is pushed downward through the crypt-space without becoming fully disorganized.

"Through the subsequent migration of round cells and endothelial or other phagocytic cells into this region, the area (the crypt-space) becomes consolidated. At the same time many of the flagellates are surrounded by endothelial cells, while others proceed to invade further the core of the villus and the muscularis mucosæ. The terminal portions of the epithelium usually remain intact at this stage.

"At this point the motile forms of the flagellates for the most part disappear, and further multiplication in the tissues is continued by autogamous reproduction. At the beginning of this stage of development most of the parasites lose both the membrane and flagella, together with other organelles which characterize the trophozoite, and appear as the round or oval bodies, staining pink with eosin, which are regarded by Smith as amebas (*Amœba meleagridis*).

"With the continued invasion of other crypts, followed by similar consolidations, the deep-lying cecal epithelium becomes to a large extent destroyed, the entire mass of cecal tissue becomes parasitized, fusions with adjacent structures may occur, and secondary bacterial infections intervene. A secondary flagellate invasion of the ceca may occur through the outer serous covering as a result of contact-infection from the liver.

"With the further progress of the infection the parasites disseminate through the reticular tissues of the core of the villi and produce a sort of 'reverse infection,' attacking from the rear the epithelium overlying the terminal portions of the villi. With the gathering of parasites between the wall and the basement membrane the epithelium is first straightened and finally forced off. This is the culmination in the process leading to a more or less complete destruction of the cecal epithelium and a liberation of some of the parasites into the cecal canal.

"In explanation of the circumstances leading to the active invasion of the crypts, the data at present in hand make it appear probable that an earlier diarrheal condition present in the lower intestine and ceca is mainly responsible for the great multiplication of the flagellates (autogamy) in the cecal canal and for the subsequent invasion of the crypts. It seems much less probable that the flagellates in themselves can be regarded as the cause of the initial diarrheal state. . . .

"True amebas, chiefly *A. intestinalis*, are frequently present in the ceca, sometimes in numbers, but only in exceptional cases can it be concluded that they are of pathogenic significance in the production of cecal lesions. Aside from those cases in which it is identical with the schizont stage of *Eimeria avium*, *A. meleagridis* must be regarded as the late trophozoite (rounded) stage of the intestinal flagellate, *Trichomonas*."

Meningo-encephalomyelitis of fowls (? spirillosis), G. URBAIN (*Bul. Soc. Path. Exot.*, 9 (1916), No. 8, pp. 561-563; *abs. in Trop. Vet. Bul.*, 4 (1916), No. 4, p. 185).—This article relates to a disease which affects a few adult fowls in most poultry runs in the State of Parana, Brazil, where it is known locally as "ar."

Fowl plague in ducks, L. COMINOTTI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 39 (1916), No. 5, pp. 129-135, figs. 2; *abs. in Trop. Vet. Bul.*, 4 (1916), No. 4, p. 176).—This reports upon a study of an outbreak of fowl pest or plague among ducks on the lake of the Public Gardens of Milan in which 50 per cent of the birds became affected. The paper includes a review of the literature. The studies led to the following conclusions:

"Fowl plague may attack wild ducks placed in the same conditions as domesticated birds. The clinical form in which the disease manifests itself in these animals is the nervous form. The morbid anatomy of the disease shows nothing characteristic. The virus can not be found in the blood or in

the internal organs, even when quantities exceeding those employed in working with the disease in geese are used. It is found, however, in the central nervous system.

"The transmission of the infection to fowls is possible by means of subcutaneous injection of emulsions of the cerebral substance of infected ducks. On the contrary it is not possible to transmit it to the domesticated duck however large a dose of virus is employed, either by ingestion, intravenous inoculation, instillation on to the conjunctiva, or even by intracerebral inoculation."

### RURAL ENGINEERING.

**Hydraulic flow reviewed, A. A. BARNES** (*New York: Spon & Chamberlain, 1916, pp. XI+158, pls. 12, figs. 15*).—This is a book of reference to standard experiments on the flow of water in pipes, channels, notches, weirs, and circular orifices, together with new formulas relating thereto derived from the author's experiments.

Part 1 deals with the experimental determination of the coefficients in the logarithmic formula for the flow of water in various kinds of pipes and channels. Part 2 deals with the measurement of water by means of triangular notches, weirs, and circular orifices, and with the abolition of the varying coefficient.

From his experiments the author draws the conclusion that flowing water always obeys one fundamental law. "As distinct from the various types of formulas which at present exist for representing isolated sets of results these new equations form one family, the individual members are all descended from the fundamental formula:  $v = K m^a H^b$ . Further, this equation is directly related to the formula for all classes of pipes and channels in which the introduction of the length in the direction of flow merely causes the formula to be written:  $v = K m^a i^b$ , in which  $i = \frac{H}{L}$ ."

A bibliography and working tables and diagrams are included.

A striking feature of this book is that no recognition is given certain recent American works bearing on the subject, especially those from the U. S. Reclamation Service and the U. S. Department of Agriculture.

**Hydro-electric power.—I, Hydraulic development and equipment, L. LYNDON** (*New York: McGraw-Hill Book Co., 1916, vol. 1, pp. VII+499, pl. 1, figs. 234*).—It is the author's purpose in this book "to produce a work for the guidance of engineers in the practical design of hydroelectric plants, which would have the characteristics of accuracy, clearness, and completeness. Scientific discussions of various hypotheses and theories have been omitted except in cases where their incorporation in the text has been essential to the understanding of the subjects treated. . . . A number of new and original formulas appear for the first time here. Among these may be mentioned the exact formulas for solid dams and for the magnitude and location of the resultants of forces acting on dams."

The successive chapters are as follows: General conditions, flow in streams, weirs and orifices, power variation and storage, artificial waterways, pipe lines and penstocks, dams, movable crests for dams, headworks, water wheels, and speed regulation of water wheels and abnormal penstock pressures. Mathematical tables for practical use are appended.

**Convenient form of hook gage, R. B. SLEIGHT** (*Engin. News, 77 (1917), No. 4, pp. 155, 156, figs. 2*).—This article describes and illustrates a convenient hook gage developed by the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture and used by its Irrigation Investigations Division.

Profile surveys in the Colorado River basin in Wyoming, Utah, Colorado, and New Mexico (*U. S. Geol. Survey, Water-Supply Paper 396 (1917), pp. 6, pls. 43*).—This report, prepared under the direction of W. H. Herron, contains a plan and profile of Green River above Fontenelle, Wyo.; Green River from the Colorado state line to Horseshoe Bend, Utah; Green, Duchesne, Uinta, and White rivers in the vicinity of Ouray, Utah; Green River from mouth to Gunnison Butte, Utah; Grand River from Green River to Castle Creek, Utah; Grand River from Grand Junction, Colo., to Castle Creek, Utah; Grand River from Kremmling to Glenwood Springs, Colo.; Gunnison River from Cimarron Creek to Gunnison, Colo.; and Gila River in the vicinity of Cliff and Redrock, N. Mex.

Irrigation in Florida, F. W. STANLEY (*U. S. Dept. Agr. Bul. 462 (1917), pp. 62, pls. 6, figs. 10*).—This bulletin deals with the history of irrigation in Florida, and states that in 1915, 25,500 acres of truck crops and citrus groves were irrigated in Florida.

The main conditions making irrigation necessary in Florida are said to be the uneven distribution of the rainfall and the character of the soils. Soil moisture determinations in citrus groves and trucking sections showed that after the moisture content has fallen below 3 per cent the available supply is exhausted. "It is apparent that cultivation in the open spaces has had a marked effect upon the soil moisture." However it is shown "that both cultivated and noncultivated groves have depleted their available moisture supply from the soil, which evidently can be supplied only by rain or irrigation. . . . It appears that it would pay to cultivate the groves during the dry weather if all possible moisture is to be conserved. . . ."

"Practically every part of the State is well supplied with water for irrigation purposes in the form of lakes, streams, or wells. The rivers are little used as an irrigation supply, either by means of diversion ditches or through the use of pumping plants, but the lakes and wells are used extensively both for irrigation purposes and for domestic supply."

The important types of irrigation practiced in Florida are described as (1) subirrigation, (2) overhead spray, (3) grove irrigation, which includes many different systems, and (4) furrow irrigation, applicable both to truck crops and to citrus groves. It is noted "that where there are uniform conditions of soil, water supply, and cropping, similar methods have been followed. This is true especially of the sections where flowing wells have been obtained. . . . What appears to be most needed to encourage the construction and operation of irrigation plants in Florida is a knowledge of cheaper installation for the higher and sandier groves, with cheap and efficient methods of distribution. Such methods are needed in many of the truck gardens and in many of the groves that lie on the lower elevations."

Tests of soil moisture content made to determine the best heads of water and length of time to be allowed for furrow irrigation are also reported. Tests in a grove in very dry sandy soil showed the rapid downward trend of the water when applied by the flood method. It is noted "that practically no water was lost by percolation or seepage below the sixth foot until more than an hour after the water had been turned off; after that time there was some loss. Water was run down a broad furrow at the rate of about 75 gal. per minute for 30 minutes." It is also shown "that water will disappear rapidly below the sixth foot if run too long. The lateral distribution is very slight, hardly a foot on either side from the edge of the furrow." When water was run only 15 minutes there was no waste of water below the third foot. Tests made with different heads showed that the distance water will run down furrows is dependent on the head provided there is some grade to the furrows. "Experi-

ments in a grove at Orlando showed that heads of 25 gal. per minute were adequate for ideal furrow-irrigation methods."

Experiments with low-pressure pipe systems are also described and some important points in the design and equipment of an irrigation plant are discussed.

**Investigations in cost and methods of clearing land**, M. J. THOMPSON (*Minnesota Sta. Bul. 163 (1916), pp. 31, figs. 26*).—Investigations on the methods and cost of clearing 15 acres of cut-over timberland at the Northeast Demonstration Farm and Experiment Station are reported.

The land averaged more than 200 stumps to the acre, these having a diameter of about 12 in. at the base and 10 in. at the cut-off. Sixty per cent of the timber was green. The soil is a somewhat stony clay loam with a clay subsoil, generally reddish, but in some places bluish gray. The timber was about 57 per cent balsam, 16 per cent birch, 13 per cent pine, 6 per cent cedar, 3 per cent tamarack, 1 per cent spruce, 1 per cent balm of Gilead, and 3 per cent miscellaneous. The lower grades of dynamite were used on all kinds of stumps except green birch, for which 60 per cent was found most efficient. The land was divided into three tracts of 5 acres each. On tract 1 the clearing was forced with dynamite. On tract 2 the stumps were first split with small charges of dynamite and then pulled with a machine. Tract 3, after being brushed out, was seeded to clover and timothy for pasturage, and clearing with dynamite was postponed 5 years, until 1918. The following conclusions from progress results were drawn:

"Cost and method are determined largely by the character of the soil and the kind of vegetation. The returns in forest products, cordwood, pole wood, fence posts, and saw logs cover the cost of brushing and other clearing work up to the stumping stage. The cost per stump for blasting and pulling on tract 2 was almost identical with the cost of explosives alone on tract 1. The cost of clearing was much less on tract 1, since much less labor was required in piling and burning the stumps.

"The cost per stump for removal was least for the man-power machine, slightly greater for the horse-power machine, and greatest for dynamite (this was for green timber and did not include the cost of piling, which makes the use of dynamite the cheapest method by a good margin). Some relation may apparently be established between the size of the stump and the size of the charge required to remove it.

"The man-power puller has a limited field where the conditions correspond to those at the Northeast Station. It works to best advantage on the small new farm where the farmer has very limited means. . . . It is evident that under conditions existing on the average farm in the region of the station dynamite is usually to be preferred to the stump puller, either alone or in combination.

"The plan of clearing being followed on tract 3 will not only be carried out at a lower cost but is actually giving a larger net return in pasturage the first year than has been realized from the first crops from land on which the clearing has been forced. . . .

"Following the removal of stumps from cut-over timberlands, on account of the shallow covering of vegetable matter, care should be taken to plow shallow the first time and to take immediate steps to increase the humus by seeding the land to clover and grasses, using barley or oats for a nurse crop."

**Public road mileage and revenues in the Southern States, 1914** (*U. S. Dept. Agr. Bul. 387 (1917), pp. 52+LXXI, fig. 1*).—This bulletin is a compilation which shows mileage of improved and unimproved roads, sources and amounts of road revenues, and bonds issued and outstanding, and presents a

description of the systems of road administration, fiscal management, and other factors affecting road improvement in the States of Alabama, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

The total revenues applied to roads and bridges in the Southern States in 1914 amounted to \$52,516,559.73, including state appropriations, amounts derived from local taxation, and expenditures from bond issues, both State and local. The total county and district road and bridge bonds outstanding on January 1, 1915, amounted to \$64,639,060.83. The total road mileage as of January 1, 1915, was 814,565, of which 73,594.78 miles, or 9.03 per cent, were surfaced. This does not include streets in incorporated cities and towns. Of the surfaced roads 29,287.88 miles were sand clay, 21,377.37 miles were macadam, 17,440.02 miles were gravel, 1,994.36 miles were bituminous macadam, 1,924.68 miles were shell, 379.81 miles were brick, 273.24 miles were concrete, and 917.42 miles were surfaced with other materials.

Earth, sand-clay, and gravel roads, C. H. MOOREFIELD (*U. S. Dept. Agr. Bul. 463 (1917), pp. 68, pls. 5, figs. 24*).—This bulletin gives general information on the location and design of roads and deals with the construction, maintenance, and cost of earth, sand-clay, and gravel roads.

With reference to grades, "tests made by the Office of Public Roads and Rural Engineering indicate that, on a level road average farm horses untrained to the road can exert a steady pull for several consecutive hours equivalent to from 0.08 to 0.1 of their own weight without undue fatigue, and that by resting at intervals of from 500 to 600 ft. they can exert a pull equivalent to about 0.25 of their weight, provided the foothold is good. The tests also indicate that with a well-constructed wagon the pull required to move a gross load of 1 ton over a level road varies about as follows: Loose-sand road, 315 lbs.; average dry earth road (varies greatly), 150; firm earth or sand-clay road, 105; average gravel road, 80; and first-class gravel or macadam road, 55. . . .

"For economy the maximum grade for any particular road should be fixed with due regard for the type of surface to be employed. Where the road is through deep sand, a horse of [1,255 lbs. weight], by extraordinary exertion, could pull his allowable continuous load of 760 lbs. for level grades up a short grade of about 10 per cent, while in the case of a firm earth or sand-clay road the allowable continuous load for level grades is 2,285 lbs., and the steepest grade up which the horse could possibly pull this load is about 5 per cent. For average gravel roads the corresponding comparison would show a maximum grade of about 4 per cent. . . . According to the best current practice, where the road is or is expected to become of sufficient importance to warrant a highly improved surface, the maximum grade usually is fixed with reference to this feature about as follows: Coastal plain and prairie regions, 2 to 3 per cent; average rolling country, 4 to 6; and hilly or mountainous regions, 6 to 8."

In dealing with gravel roads the results of a number of tests made on gravel obtained from various parts of the country with reference to its suitability for use in road surfaces are given. "In general, it has been found that satisfactory gravel will conform to the following limits as to percentages of fine and coarse material: (1) Material retained on a  $\frac{1}{4}$ -in. sieve 55 to 75 per cent, (2) material retained on a  $\frac{3}{4}$ -in. sieve not less than 15 per cent, (3) material (clay) passing a 200-mesh sieve for the surface course 8 to 15 per cent, and (4) material (clay) passing a 200-mesh sieve for the foundation course 10 to 15 per cent. The sand content should be at least twice as great as the clay content,

and the sand and clay, when thoroughly mixed, should be sufficient to fill the voids between the larger gravel particles."

An appendix on typical specifications is included.

Earth roads and the oiling of roads, H. A. LARUE (*Univ. Missouri Bul.*, 17 (1916), No. 16, pp. 29, figs. 10).—This bulletin deals with the construction, grading, and maintenance of earth roads, and with the history and general considerations as to oiling roads and selection of road oils, and with methods of oiling earth, macadam, and gravel roads. The principal items in the proper oiling of earth roads are summarized as the "proper drainage of both surface and subsurface, heavy grading done at least one season in advance of oiling, proper shaping of the roadway to form a good crown and gutters, maintenance of the surface with the road drag for some time previous to oiling to insure compact and smooth roadway, careful removal of dust before oiling (this is of the utmost importance), proper method of applying oil (includes thorough mixing of oil in earth), use of the right kind of oil (quality of oil can be determined only by proper tests), and proper maintenance after oiling and renewed oiling as needed."

Width of wagon tires recommended for loads of varying magnitudes on earth and gravel roads, E. B. McCORMICK (*U. S. Dept. Agr., Office Sec. Circ.* 72 (1917), pp. 6, figs. 6).—"The recommendations in this circular relating to widths of wagon tires suitable for use on country roads of earth and gravel, as well as upon those of a more improved type, are based upon two factors, (1) the unit weight for width of tire commonly used for road rollers, and (2) the results secured from a large series of traction tests conducted by the Office of Public Roads and Rural Engineering, extending over several years and made in widely scattered localities throughout the United States. . . .

"From the curves shown the following conclusions may be drawn for well-constructed dry earth roads: With a gross load of 5,000 lbs. the unit draft decreases with the width of tire up to and including the 5-in. width. The unit draft decreases directly as the weight per inch width of tire decreases, until a weight of 250 lbs. per inch of tire is reached. . . . The fact that the draft for a 6-in. tire is larger than that for a 5-in., in all cases shown, merely indicates that there is no advantage in increasing the width of tire beyond a certain point, and there may be a disadvantage in so doing. It is not advisable to exceed in any vehicle a unit weight per inch of width of tire in excess of that possessed by a standard road roller.

"While there has been in the past, and to a certain extent still is to-day, wide variation in sizes and types of wagons marketed by the different manufacturers, it is believed that five sizes of wagons will be sufficient to meet all the needs of farming operations and all general work except the heaviest trucking and certain specialized hauling, which is likely to be confined to city pavements. These five sizes are (1) a one-horse wagon having a gross load capacity of 2,000 lbs. and a skein from  $2\frac{1}{2}$  to  $2\frac{3}{4}$  in., (2) light two-horse wagon with a skein approximately  $2\frac{1}{2}$  in. and a gross carrying capacity of 3,500 lbs., (3) medium two-horse wagon with a skein not exceeding 3 in. and designed for a gross load of 4,500 lbs., (4) standard two-horse wagon with a skein of  $3\frac{1}{4}$  in. and a gross carrying capacity of 6,800 lbs., and (5) heavy two-horse wagon having a skein of  $3\frac{1}{2}$  in. and gross load capacity of 7,500 lbs." The widths of tire recommended for these five sizes of wagon are respectively 2,  $2\frac{1}{2}$ , 3, 4, and 5 in.

"As there is considerable difference in the practice of manufacturers regarding the size of skein used on the various types of wagons, it is recommended that wagons be not designated by size of skein but according to the gross load

capacity and that a name be adopted for each of the sizes. It is further recommended that the gross carrying capacity of the wagon be shown by stencil or plate on the back of the rear axle."

**Tests of large reinforced concrete slabs**, A. T. GOLDBECK and E. B. SMITH (*Proc. Amer. Concrete Inst.*, 12 (1916), pp. 324-334, figs. 7).—Tests of three reinforced concrete slabs to determine the distribution of stresses and the effective widths are reported. Each of the three slabs was made of 1:2:4 gravel concrete, machine mixed, and was reinforced with 0.75 per cent of plain square steel bars with no transverse reinforcing. The slabs were 32 ft. wide, of 16 ft. clear span, with a 10 in. bearing width on each support. Tests were begun at the age of about 28 days and were continued periodically until the time of breaking. One slab was broken at the age of about six months; a second at about five months; and a third at three months. The deformation values for each slab and for the different load values are shown graphically. Each curve is plotted from the deformation values measured perpendicular to the supports and spaced along the center line parallel to the supports.

The general shape of the curves for all loads is the same for the concrete and the steel. One of the important facts brought out is that the time element is a very large and important factor in determining stress values and their distribution from the fiber deformations. "Concrete exhibits a marked flow or molecular adjustment under working stresses extending over time periods of several weeks."

From a series of experiments on the flow of concrete it is pointed out that "when concrete is subjected to a compressive fiber stress of 700 lbs. the immediate fiber deformation is only about 50 per cent of what it will be if the stress is maintained for three weeks. Within 24 hours after the application of the load the deformation has increased an additional 20 per cent; during the first hour the deformation may show a change of 5 per cent or more. Furthermore the recovery of the deformations, after the removal of the load, is slow and not complete.

"All tests for stress and deformation values in concrete must be conducted only with a full realization of the importance of the time factor. The immediate fiber deformation is the value which should be used, and not the value obtained after a long-time suspension of the load, nor that which contains the effect of several applications and removals of loads."

From the data on effective width obtained when considering thickness and load and its distribution it is noted that "there is a general tendency for the effective width to increase slightly with the increase of load. Also the effective width seems to vary inversely as the thickness of the slab. In the light of the information available at the present time we should be safe in using a value for the effective width equal to 0.7 of the span. This will probably result in the design of a somewhat thinner slab than is usual; but the fiber stress values and the large ultimate breaking loads of these slabs are an indication of the safety of such designs."

**A milk house for Texas**, L. RHODES (*Texas Sta. Circ.* 15 (1916), pp. 3-7, figs. 4).—This circular describes and illustrates with plans a milk house to be built near the dairy barn and sufficient in size to provide room for handling the milk from 20 or more cows.

**Principles of poultry house construction**, M. C. KILPATRICK (*Agr. Col. Ext. Bul.* [Ohio State Univ.], 12 (1916-17), No. 2, pp. 32, figs. 37).—It is the purpose of this bulletin to discuss briefly the fundamental principles which should be considered in the housing of poultry, and to present a number of plans of poultry houses for various purposes which are well adapted to Ohio conditions.

## RURAL ECONOMICS.

Agriculture after the war, A. D. HALL (*London: John Murray, 1916, pp. VIII+137, figs. 3*).—The author discusses the present status of agriculture in England and Wales.

He concludes that "in the interests of the nation as a whole it is necessary to grow at home a larger proportion of the food we consume: (1) As a national insurance in time of war; (2) to develop our internal resources and reduce our foreign indebtedness, a matter which becomes of greatest moment in war time; (3) to increase the agricultural population as a specially valuable element in the community. . . .

"Five methods are outlined for obtaining a more intensive cultivation of the soil and providing employment upon the land. These are the establishment of large industrialized farms working on a considerable area with all the economic advantages of organization and scientific management, the establishment of colonies of small holders linked together by a cooperative organization, the intensification of the methods of existing occupiers, the reclamation and settlement of waste and undeveloped areas, the establishment of certain subsidiary agricultural industries."

Farming in the blue grass region, J. H. ARNOLD and F. MONTGOMERY (*U. S. Dept. Agr. Bul. 482 (1917), pp. 29, figs. 13*).—It was found that specialized farms, those of the tobacco, stock, or dairy type, moderately diversified, are the most efficient in this region and that the general mixed farms, more highly diversified, are the least efficient. While diversity has a vital relation to the profits in this region here as elsewhere, it appears that in the blue grass region the specialized farms have found in moderate diversity the right degree for maximum profit. "Only 34 per cent of the farms of this type could be counted as distinctly successful, while the stock-with-tobacco type had about 58 per cent successful. The dairy type, of which there were only 10, showed 70 per cent successful, with a higher average labor income and higher efficiency than any other type. Of the other three types, about 50 per cent of the farms were successful.

"The general mixed type is evidently organized on the wrong basis to be profitable. It has about the same proportion of its receipts from tobacco as the stock-with-tobacco type, but the percentage area in tobacco is very much smaller, only about 4.4 per cent, while the stock-with-tobacco type has an average of about 8 per cent of its area in tobacco. With the exception of tobacco, there seems to have been a failure to dispose of the crops raised, either by marketing them profitably or by utilizing them to advantage through live stock. Many with large farms and large capital seem to have been satisfied with bare interest on their investment, which was adequate for a comfortable living. These men made no effort to make the farm a business success. The tobacco area and much of the area of other crops on such farms was in most cases cultivated by cropper labor, which relieves the owner of much responsibility. . . .

"The farmer who can command but a small area of land should, in order to make his farm most profitable, specialize in tobacco or, where market conditions permit, in dairying. On farms of from 260 to 360 acres in size the best results can be obtained by organizing on the basis of the stock-with-tobacco type, which emphasizes live stock but cultivates an area in tobacco large enough to utilize labor resources to advantage and to secure the advantage of diversity."

Agriculture in the Imperial Valley, W. E. PACKARD (*California [Sta.] Circ. 159 (1917), pp. 70, figs. 20*).—This circular was prepared to give both new and old settlers in southern California information as to the best methods to be followed in farming there. The author describes the soil characteristics, cli-

matic conditions, water supply, irrigation, and the adaptability of a large number of crops to this region, indicating the best methods for growing, the usual yields obtained, market ability, and the most usual insect pests and diseases found. Soil analyses are included.

Facts about Georgia, compiled by L. N. GELDERT (*Atlanta, Ga.: Ga. Chamber Com., 1916, pp. 277, figs. 185*).—In this volume are discussed the resources of the State, its agriculture, manufactories, mining, and forestry.

The cost of living on Minnesota farms, 1905–1914, F. W. PECK (*Minnesota Sta. Bul. 162 (1916), pp. 3–31, figs. 10*).—The farms from which this data were gathered are those previously mentioned (E. S. R., 32, p. 688).

The total average cost of living (food, labor, equipment, fuel, and rent) was \$816.63 per family, or \$162.12 per person. Of the total cost, cash groceries constituted 24 per cent, farm produce 22.1 per cent, labor 28.7 per cent, equipment 5 per cent, fuel 7 per cent, and rent 13.2 per cent. The actual cash spent annually per person for farm living was \$54.08, or 32.6 per cent of the total cost. Of this amount 72 per cent was for the purchase of food and the rest for fuel and labor. Of the total value of food 52 per cent was spent for groceries, 38.7 per cent representing animal products from the farm, and 9.3 per cent vegetables grown on the farm. Details are given for the different areas and for the different items of expense.

Labor requirements of live stock, A. BOSS, F. W. PECK, and T. P. COOPER (*Minnesota Sta. Bul. 161 (1916), pp. 3–43, figs. 8*).—The records upon which this bulletin is based were obtained from the same sources as those mentioned above (E. S. R., 32, p. 688). The authors have summarized their findings as follows:

*Total hours required annually per head of live stock.*

Kind of stock.	Northfield.		Marshall.		Halstad.		1,920-acre farm.		Average, all farms.	
	Man.	Horse.	Man.	Horse.	Man.	Horse.	Man.	Horse.	Man.	Horse.
	<i>Hours.</i>	<i>Hours</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>	<i>Hours.</i>
Horses.....	78.8	3.6	72.2	9.9	97.4	11.8	91.5	13.7	83.7	9.6
Cows.....	143.0	39.6	128.0	27.7	158.2	22.4	228.7	25.8	148.0	31.8
Miscellaneous cattle.....	17.3	.....	7.0	.....	13.5	.....	12.8	.....	11.1	.....
Hogs.....	12.5	2.6	9.0	2.4	27.6	4.1	24.8	1.3	12.1	2.6
Sheep.....	3.3	.4	2.3	.6	5.0	.7	.....	.....	2.9	.6
Poultry (100).....	124.0	5.5	145.0	16.0	141.0	8.6	265.0	.....	141.2	9.6

Details are also given showing the distribution of labor requirements by months not only for live stock but also for crops.

Farmers' elevators in Minnesota, 1914–15, E. D. DURAND and J. P. JENSEN (*Minnesota Sta. Bul. 164 (1916), pp. 43, figs. 5*).—This report indicates that on January 1, 1916, there were 296 cooperative elevators in the State, which constituted about one-fifth of the total number of elevators and local mills buying grain from farmers. The bulletin points out their geographic distribution, extent of business transacted, membership, capital stock, receipts, expenses, profits, and commodities handled other than grain.

The returns indicated that the cooperative elevators received two-fifths of the grain handled by all elevators in the State, and that the operating expenses were 2.6 per cent of the gross receipts, and the profits 2.7 per cent. Of the commodities handled by elevators, 112 reported the handling of coal, 88 feed, 71 flour, 51 twine, 30 salt, 17 seed, and 13 machinery. A small number of others reported the handling of wood, lumber, tile, cement, fencing, and oil.

A list of the farmers' elevators in Minnesota is included.

[Mutual insurance companies in Illinois] (*Ann. Ins. Rpt., Ins. Supt. Ill., 48 (1916), pt. 1, pp. 86-103*).—These pages contain data regarding the status and transactions of the local mutual fire, cyclone, tornado, and wind-insurance companies during the year 1915.

Information for prospective settlers in Alaska, C. C. GEORGESON (*Alaska Stat. Circ. 1 (rev., 1917), pp. 30, pls. 5*).—This circular continues the information previously noted (E. S. R., 35, p. 295) regarding agriculture in Alaska, and adds data regarding the new homestead laws and the regulations issued by the Secretary of Agriculture for the protection of deer, moose, caribou, sheep, and mountain goats.

Public range lands—a new policy needed, R. ADAMS (*Amer. Jour. Sociol., 22 (1916), No. 3, pp. 324-351*).—The author discusses the results of the present policy of range land management and suggests changes which are deemed necessary to bring about better social and economic conditions. The discussion relates primarily to conditions in Nevada.

[Agriculture in Canada] (*Canada Yearbook, 1915, pp. 137-228, pls. 2*).—Statistical data are given for Canada regarding the climate, meteorology, average and total yield and value of the principal crops, number of live stock, stocks of wheat, prices, and freight rates, and the production of principal crops and forest products, and the number of live stock of the principal countries of the world.

Information regarding agriculture in Pinar del Rio, Cuba, A. FONTANA (*Informe General sobre las Condiciones Economico-agricolas Actuales de la Zona de la Costa Norte de la Provincia de Pinar del Rio, desde Guanajay a Guane. Habana: Sec. Agr., 1916, pp. 63, pls. 5*).—In this report are discussed the topography, climate, distribution of cultivated plants and their production, and economic conditions affecting agricultural development in this locality.

Report and tables relating to Irish agricultural laborers (*Dept. Agr. and Tech. Instr. Ireland, Agr. Stats. 1915, pp. 20*).—This report continues the information previously noted (E. S. R., 34, p. 289).

[Agriculture in Denmark], W. J. HARVEY and C. REPPEN (In *Denmark and the Danes. London: T. Fisher Unwin, Ltd., 1915, pp. 103-116, pl. 1*).—In these pages are discussed the system of land tenure, typical Danish farms, the co-operative dairy, methods of production and distribution of raw milk, and the application of scientific methods to the farming in Denmark.

[Agricultural statistics of Spain] (*An. Estad. España, 2 (1915), pp. 64-111*).—In these pages are given, by provinces, the area, value, and production of the principal crops, together with the number of live stock.

[Agricultural statistics of Spain] (*An. Estad. España, 2 (1915), pp. 64-111*).—E. A. NOBBS and F. EYLES (*Rhodesia Agr. Jour., 13 (1916), No. 6, pp. 784-799, pl. 1*).—In these pages are given, by Provinces, the total land area, the cultivated area, and the area in the principal crops grown by Europeans, with comparative data for earlier years.

Australia for farmers (*Melbourne: Dept. External Affairs, 1915, pp. 163, pl. 1, figs. 176*).—In this volume there have been discussed in a popular manner the physical features, climatic conditions, crops grown, methods of harvesting and marketing, and live stock production. It also contains information regarding the assistance which is given to agricultural settlers.

## AGRICULTURAL EDUCATION.

The agricultural college, F. A. WAUGH (*New York: Orange Judd Co., 1916, pp. XIII+260*).—This is a discussion, from the point of view of the teacher, of the agricultural college—its purposes and ideals, organization, physical and

financial problems, organization of instruction, specialization in agriculture, courses of study (materials and arrangement, methods of teaching, extension teaching), the experiment station, and special problems and methods (farm experience, field camps, field excursions and field laboratory work, judging work, and the summer vacation).

In summarizing, the author holds that the two main purposes and ideals of agricultural schools and colleges are to give technical training, primarily, and personal human culture. There are two principal methods of providing the technical training, the first offering a broad foundation of science upon which a superstructure of technique can be built, and the second beginning with observation and practice and calling upon science for necessary explanations. The former has been the more common in the past but is considered pedagogically and practically inferior to the second, inasmuch as science should follow agriculture in the curriculum. In the author's opinion the course of study should be made up by a board of specialists more or less trained in the problems of education.

For securing correlation of departmental work the following three principal methods are found in vogue: (1) The formation of large departments with many specialist assistants; (2) the grouping of related departments into larger divisions headed by deans or division chiefs; and (3) the obliteration of department lines and the organization of the work about men or problems.

It is recommended that the different forms of agricultural teaching, viz. graduate teaching, the bachelor's or four-year course, the two-year course, the short courses, and extension teaching, should be more clearly separated than they have been in the past. Graduate work in technical agriculture, now greatly needed, should be organized on a different basis and pursued by quite different methods than is the work in existing graduate schools which are adapted to science teaching. For the immediate future such agricultural graduate courses should give considerable normal school work.

As regards specialization, which has been a great factor in the development of the agricultural college, no department should give more than 10 undergraduate courses. The technical subjects (agriculture, horticulture, and domestic arts) are essential for vocational training and must command the whole curriculum, while all other subjects must support them and be taught in sympathy with the professional point of view.

With reference to pedagogical methods now in use, in the author's opinion the professional field camps offer one of the best methods in sight for technical instruction in agricultural and horticultural subjects. The textbook method is better in the lower grades, but should not be used alone. The lecture method is the poorest and should be used as little as possible, while the new type of laboratory work, called the project method, is worthy of wider application, not only in high schools but in college work. Finally, however, more depends on the teacher than on the pedagogical methods adopted.

The colleges are deemed justified in making farm experience a requirement for matriculation, but unless the students lacking such experience are strictly excluded, the college should make serious effort to supply the deficiency before graduation.

Report of a survey made for the Milwaukee Taxpayers' League, W. MATSCHECK (*Madison, Wis.: Wis. Efficiency Bur., 1916, pp. 73*).—This survey of the Milwaukee County School of Agriculture and Domestic Economy contains a report on the organization, history, land, buildings and equipment, students, graduates, courses of study, teaching staff, teaching, extension activities, school farm, and school finances, with a discussion and recommendations and a summary of findings.

Canada's intellectual status and intellectual needs, A. BAKER (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), pp. XXXIX-LXXII*).—In this discussion of the intellectual status and needs of the people of Canada the author includes a review of the extent to which technical and agricultural instruction has been introduced into the various Provinces.

Agricultural education and research in Canada, F. T. SHUTT (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), Sect. III, pp. 1-17*).—The author discusses the status of agriculture in Canada, the value of science in agriculture, and the improvement of the practice of agriculture in Canada through education, demonstration, and research.

[Agricultural education and research in the Province of Quebec, 1914-15] (*Rpt. Min. Agr. Proc. Quebec, 1915, pp. XX+284, pls. 53, figs. 8*).—This report on the progress in the work of the department of agriculture for the Province of Quebec in 1914-15 includes an account of the work of the agricultural and domestic-science schools, experiment stations, and extension work under the control of the department.

Report of the schools' division of the experimental union, S. B. MCCREADY (*Ann. Rpt. Ontario Agr. and Expt. Union, 37 (1915), pp. 49-60*).—A general survey is given of the origin, purposes, and accomplishments of the schools' division of the Ontario Agricultural and Experimental Union. This division, begun in 1909, is a cooperative association in education which grew out of this union and the nature-study department organized as a part of Macdonald Institute in 1904.

School gardens, 1915, J. C. MAGNAN (*Les Jardins Scolaires, 1915. Quebec: Min. Agr., 1916, pp. 16, pls. 6; Rpt. Min. Agr. Prov. Quebec, 1915, pp. 215-227, pls. 4*).—In this report of progress in school garden work in the Province of Quebec the author discusses some difficulties met and their solutions and interesting results. It is shown that the number of pupils taking school-garden work increased from 425 in 1906 to 9,308 in 1914, and the number of schools having gardens from 60 in 1907 to 284 in 1914.

The teaching of household science (*Agr. Gaz. Canada, 3 (1916), No. 12, pp. 1093-1103*).—This is an account of the present status of instruction in home economics in the Provinces of Nova Scotia, Ontario, Manitoba, Saskatchewan, and Alberta.

Agricultural education for women (*Rpt. Agr. Ed. Conf. [Gt. Brit.], 1915, pp. 84*).—This report on agricultural education for women in England and Wales is based on an inquiry made at the request of the Board of Agriculture and Fisheries. It considers (1) the conditions affecting the instruction of women in agriculture, including the scope of agricultural education and the different classes of women for whom agricultural instruction is needed; (2) the existing facilities for the instruction of women in agriculture, classified as itinerant instruction, farm schools or institutes, agricultural and horticultural colleges, and university institutions; and (3) women's agricultural institutes.

The conference concludes that itinerant instruction should take the form of organized classes rather than that of lectures, and every part of a county should be covered in a definite cycle of years. The number of farm schools or fixed courses of instruction should be so increased as to provide one for every county or two counties. A systematic long course for women, covering all branches of agricultural work (practical and scientific), should be organized at one of the existing agricultural colleges. Scholarships from itinerant classes to farm schools and from farm schools to collegiate institutions, as well as for the daughters of the larger farmers and professional men at collegiate centers, should be provided. Home economics should form part of the curriculum in every organized course. A training course for poultry teachers

should be given at one of the existing agricultural colleges and a national examination in poultry be held. At least two women members should be added to the county committees of agricultural education and a woman should be employed in inspection work by the Board of Agriculture and Fisheries, and the organization of women's institutes should be encouraged.

Summaries of oral evidence before the conference, statistics on the employment of women in agriculture, and a memorandum by the secretary on the facilities for agricultural education for women in England and Wales, the extent to which women are and might be employed in agricultural work in England and Wales, with particulars of the farm operations performed and particulars of scholarships free to women students in agricultural courses in 1914-15, are appended.

Agricultural reeducation of the maimed (*Vie Agr. et Rurale*, 6 (1916), No. 49, pp. 401-424, figs. 28).—This number is devoted to a description of the facilities in France for the agricultural reeducation of soldiers maimed in the war.

Our field and forest trees, MAUD GOING (*Chicago: A. C. McClurg and Co., 1916*, pp. [10]+222, pls. 18, figs. 35).—This book, which is intended for the high school student and the "man in the street," treats of the various parts of the tree, together with their functions, wasteful lumbering and tree diseases, the relation of woods, river, and the rain, the uses of wood, and the question of a wood famine, forest fires. U. S. National Forests, Canadian forest reserves, and the forester and his work. The book is arranged in seasonal sequence for the convenience of the teacher and endeavors to avoid technical terms and phrases.

Exercises in poultry husbandry for high schools, W. E. EVANS and F. G. BEHREND (Ithaca, N. Y.: *Authors, 1916*, pp. 78, fig. 1).—Thirty-nine laboratory exercises in poultry husbandry, adapted to the needs of high schools, are outlined. They include a poultry survey and a study of the fowl, parasites, incubation, brooding, the egg, the preparation of poultry products, poultry houses, feeds, identification of varieties, a visit to a poultry show, and a critical examination of a poultry farm. Two-week schedules for 10 students in a poultry course, in conjunction with farm shop work, are suggested. An appendix in 36 parts, consisting of questions and references to literature, may be used for review or as work in connection with the student's preparation for the home project.

List of workers in subjects pertaining to agriculture and home economics in the U. S. Department of Agriculture and in the state agricultural colleges and experiment stations (*U. S. Dept. Agr., List of Workers in U. S. Agr., 1917*, pp. 88).—This is the annual organization list of workers along these lines (*E. S. R.*, 34, p. 94), corrected to January, 1917.

### MISCELLANEOUS.

Report on agricultural experiment stations and cooperative agricultural extension work in the United States for the year ended June 30, 1915 (*U. S. Dept. Agr., Rpt. Agr. Expt. Stas. and Coop. Agr. Ext. Work, U. S., 1915*, pp. 321+364, pls. 12).—This report, prepared by the States Relations Service, consists of two parts.

Part 1 includes the usual report on the work and expenditures of the agricultural experiment stations in the United States, including Alaska, Hawaii, Porto Rico, and Guam, together with detailed statistics compiled from official sources as to the organization, revenues, additions to equipment, and expenditures of the stations.

The total income of the stations during the fiscal year 1915 was \$5,286,332.53. Of this amount \$718,679.91 was derived under the Hatch Act, \$719,699.66 under the Adams Act, \$2,129,604.04 from State appropriations, \$23,003.49 from individuals and communities, \$343,087.66 from fees, \$514,220.47 from farm products, and \$716,466.87 from miscellaneous sources. The value of additions to the equipment of the stations was estimated at \$1,135,980.04, of which \$537,665.45 was for buildings.

The stations employed 1,857 persons in the work of administration and inquiry. Of this number 892 were also members of the teaching staff of the colleges and 466 assisted in farmers' institute and other extension work. During the year the stations published 1,676 annual reports, bulletins, and circulars, aggregating 30,867 pages, and these were distributed to 1,114,261 addresses on the regular mailing list.

Part 2 comprises a report on the receipts, expenditures, and results of cooperative extension work in agriculture and home economics in the United States. Of this, pages 13-144 are devoted to Extension Work in the South, pages 145-326 to Extension Work in the North and West, pages 327-334 to Farmers' Institute Work, 1915, by J. M. Stedman, and pages 335-353 to statistics of farmers' institute and extension work. The text of the Smith-Lever Act is appended.

Twenty-ninth Annual Report of Indiana Station, 1916 (*Indiana Sta. Rpt. 1916, pp. 100, figs. 8*).—This contains the organization list, reports of the director and heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and a financial statement for the federal funds for the fiscal year ended June 30, 1916, and for the remaining funds for the period ended September 30, 1916.

Twenty-ninth Annual Report of Michigan Station, 1916 (*Michigan Sta. Rpt. 1916, pp. 241-868, figs. 111*).—This contains reports of the director and heads of departments on the work of the station during the year, the experimental features of which are for the most part abstracted elsewhere in this issue; a financial statement for the fiscal year ended June 30, 1916; and reprints of Bulletin 275, Special Bulletins 74-79, Technical Bulletins 20-27, and Circulars 28-30, all of which have been previously noted.

Monthly Bulletin of the Ohio Experiment Station (*Mo. Bul. Ohio Sta., 1 (1916), No. 12, pp. 353-391, figs. 15*).—This contains several articles abstracted elsewhere in this issue, and Winter Heating of Peach Orchards, by W. J. Green.

## NOTES.

---

**California University and Station.**—A state survey of crop and live stock conditions in California and the possibility of increasing production was conducted during April by members of the staff of the College of Agriculture, cooperating with the various state officials, the Forest Service of the U. S. Department of Agriculture, and others.

Recent promotions and changes in title include the following: As professors, L. D. Batchelor in plant breeding (in the Citrus Substation and Graduate School of Tropical Agriculture at Riverside), B. A. Etcheverry in irrigation engineering, and C. L. Roadhouse in dairy industry; as associate professors, R. L. Adams and P. B. Kennedy in agronomy, and D. N. Morgan in agriculture (and assistant to the director of the station); as assistant professors, H. S. Baird in dairy industry (at the University Farm at Davis), G. P. Gray in entomology (and chemist in the insecticide laboratory), W. H. Heilemann in agricultural extension, A. H. Hendrickson in pomology, G. W. Hendry in agronomy, P. L. Hibbard in agricultural chemistry, and W. P. Tufts in pomology (at the University Farm); and as instructors, E. O. Amundsen and J. W. Mills in agricultural extension, J. R. Beach in veterinary science, Earl Bisbee in dairy industry, A. W. Christie in agricultural chemistry, W. C. Dean in soil technology, P. T. Peterson in veterinary science (in charge of serum manufacture), and W. L. Sweet in pomology. George H. Hart has been appointed professor of veterinary science; J. C. Bradley, of Cornell University, assistant professor of entomology for one year in exchange with E. C. Van Dyke; H. M. Butterfield, instructor in agricultural extension; R. W. Hodgen, instructor in citriculture; G. F. Fermery, assistant in agricultural engineering; and J. C. Martin, assistant in agricultural chemistry. Leave of absence was granted for the ensuing year to H. S. Fawcett, associate professor of plant pathology in the Citrus Substation and Graduate School of Tropical Agriculture, and to N. L. Gardner, assistant professor of botany, from July 1 to January 1, 1918.

**Delaware College and Station.**—The increased state appropriations to the agricultural department have made possible a considerable enlargement of the station staff. A new division of plant physiology has been organized, with Ernest M. R. Lamkey, Ph. D., of the University of Illinois as its head, beginning about April 16. W. J. Young has been appointed assistant in horticulture beginning April 1, C. E. Neff, assistant in agronomy beginning April 16, and M. O. Pence, assistant state leader of county agent work in the extension service, beginning July 1.

**Georgia College.**—John M. Purdom, jr., was succeeded as editor, May 1, by H. T. Maddux.

**Idaho University.**—President M. A. Brannon has tendered his resignation.

**Massachusetts College.**—About 40 acres of land, previously not used for production purposes, are to be under cultivation to increase the food supply. A part of this area has been in lawn and another tract was originally set aside for recreation purposes.

College credit for the remainder of the term has been granted to students enlisting in military or other forms of mobilization duty, or to engage in food-production service. On May 1 only about 100 students remained at the institution.

The attendance at Farmers' Week this year reached over 800.

**Minnesota University.**—On May 5, after a general exodus to engage in various forms of agricultural or military service, only 30 men were left in the College of Agriculture. Many of these were enrolled in three special short courses instituted for preparing traction engineers, extension field assistants, and directors of school and community gardens.

**Nebraska University and Station.**—Under an act of Congress, signed March 3, the Secretary of the Interior is authorized to transfer to the university for use in dry land experiments, a tract of about 800 acres of public land adjoining the Scottsbluff Substation.

**New Jersey College and Stations.**—An act of the recent legislature changes the method of appointment of members of the board of managers of the State Station. The new system provides for a board of 21 members, one from each county. This change from the basis of appointment by Congressional districts is expected to increase the representation of the rural sections on the board.

Julian Miller and A. M. Hulbert have succeeded L. G. Gillam and W. H. McCallum, respectively, as extension specialist in fruit growing and state leader of boys' club work. W. S. Krout has resigned as assistant in plant pathology to become field plant pathologist in the Massachusetts Station. Charles H. Nissley has been appointed specialist in the extension division.

**Cornell University.**—The legislature has appropriated \$779,401 for the College of Agriculture for the ensuing year, in addition to an earlier emergency grant of \$55,910 for the present year and \$42,000 for printing. Of the new appropriation, \$34,000 is allotted for new construction and improvements, of which \$12,000 is for an additional unit to the central heating plant, \$7,000 for a new piggery, and \$1,000 for a packing shed on the pomology grounds.

The university graduated on March 29 all seniors in good standing who might wish to serve their country in military service or industrial pursuits, and granted "leave of absence without prejudice" to other students under the same conditions. By April 27, 507 leaves of absence had been granted in the College of Agriculture and further leaves were being issued at the rate of from 25 to 30 per day. Of those already granted, 144 students were in the Army or Navy or in munitions plants, 10 were under military training at the university, and 353 were on farms or other agricultural activities.

R. I. Scoville, instructor in dairying, has resigned to become assistant professor in dairy manufactures in the Oregon College, beginning in March. B. W. Shaper, instructor in extension teaching, has been appointed assistant director of the extension service at the Massachusetts College, beginning March 1. Benjamin Smith has been appointed assistant in plant pathology.

**Oklahoma College and Station.**—A science building to cost \$100,000 was authorized by the last legislature.

Glen Briggs, student assistant in the college and station, resigned March 27 to become agronomist at the Guam Station, and has been succeeded by Roy T. Hoke of the senior class.

**Porto Rico Federal Station.**—William P. Snyder has been appointed plant breeder.

**South Dakota College and Station.**—Appropriations made by the state legislature include \$80,000 for an armory, \$100,000 for the completion of Agricultural Hall, \$10,000 for a health laboratory, \$10,000 for the manufacture of hog cholera serum, \$20,000 for a fireproof stock judging pavilion, \$3,000 for a poultry department, \$10,000 for the purchase of pure bred live stock, and \$5,000 for feeding experiments with live stock. This is the first appropriation made by the State for experimental work. It is desired to take up some experiments with poultry, as this is becoming an important industry in the State.

Thomas D. Potwin of Lemon has been appointed a member of the Regents of Education, vice A. M. Anderson of Sturgis.

**U. S. Department of Agriculture.**—Dr. B. T. Galloway of the Department and President R. A. Pearson of the Iowa College have been appointed assistants to the Secretary of Agriculture. Dr. Galloway's duties are primarily to act as the representative of the Department in matters connected with the Council of National Defense, while President Pearson will especially assist the Department in keeping in touch with the state boards of food production and conservation which are being organized.

A departmental committee, consisting of R. A. Oakley, chairman, L. M. Estabrook, W. A. Wheeler, J. E. W. Tracy, Wm. Stuart, C. P. Hartley, A. J. Pieters, and C. W. Warburton, has been appointed to secure information as to the available supplies of seed for staple food crops, and to devise methods of meeting shortages in particular regions.

A survey by the Department of the farm-labor situation in the various States is contemplated. Steps are also being taken to place a representative in each State to cooperate with other agencies in organizing farm labor and assist farmers in receiving an adequate supply.

Two new divisions have been established in the Bureau of Animal Industry beginning May 1. One of them is the tuberculosis eradication division, to take charge of work which is to be considerably enlarged under the new appropriation act. The other is the tick eradication division, which will deal exclusively with this campaign, leaving the field inspection division free to devote itself to the enforcement of the cattle transportation laws and the combating of miscellaneous animal diseases.

**Fourth National Conference on Rural Education.**—This conference was held at the University of Pennsylvania, April 8 to 11, under the auspices of the U. S. Bureau of Education. The attendance was about 175, representing over 20 States.

The opening day's session dealt with religious agencies in rural life and rural education. The remainder of the program considered a nation-wide plan for the improvement of rural schools and the development of rural leadership.

Among the resolutions adopted were those favoring means to provide more adequate preparation of rural teachers, the consolidation of rural schools where practicable, and the maintenance of a teachers' home and a demonstration farm of five or more acres as part of the school property. The utilization of the country school as an intellectual, industrial, educational, and social center for community organization, the readjustment of courses of study in elementary and secondary schools to adapt them to the needs of rural life, and the provision of high school education for all country boys and girls without severing home ties, were also advocated. A special recommendation for the present emergency was for the mobilization of the boys of high school age in cities and towns into an industrial army as farm cadets, to be employed by farmers during their busy season under state and national supervision and to receive school credits as well as pay for their labors.

**Agricultural Education and Research in Great Britain.**—A movement is on foot to raise a fund of \$750,000 for the erection of new science buildings at the University College of North Wales "as a memorial to the men of North Wales who have fallen in the war." A gift of \$100,000 has already been secured. It is announced that special prominence is to be given in the new buildings to agriculture and forestry.

The Southeastern Agricultural College at Wye, England, has organized a research and advisory department distinct from the teaching side of the college and governed by a separate representative committee, composed in part of re-

search workers at the institution and in part of other scientific men. Some of the work in progress and in contemplation includes problems connected with the general practice of fruit growing, the biological study of flax, the conservation of fruits and vegetables, pasture studies, diseases of sheep, hop breeding, and fungus diseases and insect pests and their treatment by spraying.

**Agricultural Education and Experimentation in China.**—Considerable attention is now being devoted in China to agricultural education and experimentation in various classes of institutions. An experiment station was located at Peking in 1907 under the control of the board of agriculture, industry, and commerce. An experimental tract of nearly 300 acres is available, and departments of crops, soils, animal husbandry, horticulture, floriculture, entomology, botany, forestry, bacteriology, and biology have been put in operation. In 1908 an agricultural college was organized in connection with the station, but this was disbanded in 1915.

Subsequently an agricultural college and experiment station was established at the capital of each province along much the same lines as at Peking, and many other stations in addition. There are now reported to be 130 stations in the 22 provinces, of which 31 are in Chihli, 25 in Szechwan, 15 in Hu-Long-Kiang, 7 in Hupeh, and 7 in Kwangtung.

Among these are two cotton experiment stations, one at Cheng Ting Hsien, Chihli, and one at Nan T'ung Chou, Kiangsu, with a third under consideration at Tung Haing Chou, Hupeh. Experiments are being conducted at these stations in seed selection, seed distribution, plant harvesting, soils and manures, treatment of pests, and cotton weaving. A corps of students is also being trained at these stations. H. H. Jobson is in charge of the organization of the cotton work, with H. K. Fung as associate.

Stock-raising experiment stations have been established at Kalgan and Shih Men Shan, Anhui. These are expected to study the improvement of breeds of domestic animals, promote the breeding and sale of stock and stock raising enterprises, and the cultivation of forage crops.

Considerable attention is also being devoted to forestry in China. A department of forestry was organized in January, 1916, with a forestry commissioner in each province. Forestry experiment stations and training schools have been established at Ch'ang Ch'in Hsien, Shantung, and in the Temple of Heaven at Peking.

The university at Nanking has maintained a college of agriculture and a school of forestry for several years. This is an American-supported institution, and in 1915 had enrolled about 70 students in agriculture. A colonization association has been organized under its auspices, with provision for the reservation of about 35 acres in each colony for a model farm. A tract already purchased on Purple Mountain, just outside Nanking, is to be used as an experiment station in connection with the different colonies.

An agricultural experiment station was opened at Nanhsuchou, Anhwei, in 1915, as a part of the American Presbyterian mission station. Agricultural work was taken up at this institution partly as a practical way to teach Christianity, partly to make friends, and partly to improve economic conditions. The station is located on the railway between Nanking and Tientsin, and attempts to serve an area of about 6,000 square miles and from 1,500,000 to 2,000,000 people. The farming methods in use are those of from one to two thousand years ago. Special prominence is being given in the experimental work to seed selection, better tillage methods, more and better fertilization, drainage, and animal husbandry. The work is to be largely of a demonstration nature during the present pioneer stage, and will also include an agricultural

school, a school farm, and short winter courses for farmers. J. Lossing Buck has been in charge of the agricultural work at the station from the outset.

**Necrology.**—Professor Herbert W. Conn, widely known as a pioneer worker in dairy bacteriology in this country, died at Middletown, Connecticut, April 18.

Professor Conn was born at Fitchburg, Massachusetts, January 10, 1859, was graduated from Boston University in 1881, and received the Ph. D. degree from Johns Hopkins University in 1884. His long period of service was spent entirely with Wesleyan University, commencing as instructor in biology in 1884, as assistant professor from 1886 to 1889, and subsequently as professor of biology. He was also bacteriologist of the Connecticut Storrs Station from 1890 to 1896, a member of the Board of Control of the Connecticut State Station since 1908, director of the Cold Spring Harbor Biological Laboratory from 1889 to 1907, and director of the laboratory of the Connecticut State Board of Health since 1905. He was likewise closely associated with the New York Milk Committee and numerous health organizations and related bodies.

Professor Conn's work covered a large range of scientific inquiry, but he specialized in the bacteriology of dairy products. He was one of the earliest workers in this country on problems connected with certified milk, the use of pasteurized cream and pure bacterial cultures in butter making, and the bacteriological examination of municipal milk supplies. He was the author of several text books, mostly on bacteriological subjects, of which his *Agricultural Bacteriology* is especially well known. He had also contributed over 150 scientific memoirs and other articles, many of these appearing in publications of the Connecticut Storrs Station. He was one of the founders, and for 15 years president, of the Society of American Bacteriologists.

**New Journals.**—*Abstracts of Bacteriology* is the title of a new bi-monthly abstract journal published by the Society of American Bacteriologists, with A. Parker Hitchens as editor, George H. Smith as associate editor, and a numerous corps of abstract editors and abstractors. The initial number contains, in addition to abstracts of current literature and book reviews, a list of the periodicals to be reviewed and a summary of the scientific proceedings of the eighteenth annual meeting of the society, held at New Haven, Connecticut, December 27–29, 1916.

With the year 1917 *Forestry Quarterly*, which completed its fourteenth volume in December, 1916, will be amalgamated with the *Proceedings of the Society of American Foresters* under the title *Journal of Forestry*. The new magazine is to be published in eight monthly issues, containing approximately as many pages as the two original publications together. It is announced that the character of the new journal will remain essentially the same as the present publications.

*Veterinary Review* is a new quarterly published in London and Edinburgh, with Dr. O. C. Bradley, principal of the Royal (Dick) Veterinary College of Edinburgh, as editor. The initial number contains a brief article by R. G. Linton on Feeding and Economy, and about 95 pages devoted to abstracts of current veterinary literature, book reviews, and an extensive bibliography.

*The Journal of the Board of Commissioners of Agriculture, Porto Rico*, is being published under the direction of W. V. Tower, director of the Insular Experiment Station, and with John A. Stevenson as editor. The initial number contains A List of the Coccidæ of Porto Rico, by T. H. Jones, and History and Cause of the Rind Disease, by J. R. Johnston.

The Secretary of Agriculture, Commerce, and Labor of Cuba is publishing a monthly periodical known as *Agriculture*. This publication is to be devoted entirely to agricultural extension articles for the purpose of bringing the farmers into close touch with agricultural progress.

## THE AGRICULTURAL EXPERIMENT STATIONS.

### ALABAMA—

College Station: Auburn; J. F. Duggar.<sup>1</sup>  
 Canebrake Station: Uniontown; L. H. Moore.  
 Tuskegee Station: Tuskegee Institute; G. W. Carver.<sup>1</sup>

ALASKA—Sitka: C. C. Georgeson.<sup>2</sup>

ARIZONA—Tucson: R. H. Forbes.<sup>1</sup>

ARKANSAS—Fayetteville: M. Nelson.<sup>1</sup>

CALIFORNIA—Berkeley: T. F. Hunt.<sup>1</sup>

COLORADO—Fort Collins: C. P. Gillette.<sup>1</sup>

### CONNECTICUT—

State Station: New Haven; } E. H. Jenkins.<sup>1</sup>  
 Storrs Station: Storrs;

DELAWARE—Newark: H. Hayward.<sup>1</sup>

FLORIDA—Gainesville: P. H. Rolfs.<sup>1</sup>

GEORGIA—Experiment: J. D. Price.<sup>1</sup>

GUAM—Island of Guam: C. W. Edwards.<sup>1</sup>

### HAWAII—

Federal Station: Honolulu; J. M. Westgate.<sup>2</sup>  
 Sugar Planters' Station: Honolulu; H. P. Agee.

IDAHO—Moscow: J. S. Jones.<sup>1</sup>

ILLINOIS—Urbana: E. Davenport.<sup>1</sup>

INDIANA—La Fayette: A. Goss.<sup>1</sup>

IOWA—Ames: C. F. Curtiss.<sup>1</sup>

KANSAS—Manhattan: W. M. Jardine.<sup>1</sup>

KENTUCKY—Lexington: A. M. Peter.<sup>1</sup>

### LOUISIANA—

State Station: Baton Rouge;  
 Sugar Station: Audubon Park,  
 New Orleans; } W. R. Dodson.<sup>1</sup>  
 North La. Station: Calhoun;

MAINE—Orono: C. D. Woods.<sup>1</sup>

MARYLAND—College Park: H. J. Patterson.<sup>1</sup>

MASSACHUSETTS—Amherst: W. P. Brooks.<sup>1</sup>

MICHIGAN—East Lansing: R. S. Shaw.<sup>1</sup>

Cost of crushing limestone on the farm, Herron.....	821
Cost of ground limestone, Montgomery.....	822
Special fertilizer analyses, 1916, Rose and Wilson.....	822
Official fertilizer analyses, 1916, Rose and Wilson.....	822
Inspection of commercial fertilizers, 1916, Haskins, et al.....	822

## AGRICULTURAL BOTANY.

The physiology of cell division, Haberlandt.....	822
On the liquid pressure theory of the circulation of sap in plants, Baker.....	822
Cryoscopic constants of expressed vegetable saps in deserts, Harris et al.....	823
Depression of freezing point in triturated tissues, Hibbard and Harrington.....	823
Studies of protoplasmic permeability, I, Delf.....	823
Further studies on foliar transpiring power in plants, Bakke and Livingston..	824
An index to represent both moisture and temperature conditions, Livingston..	824
The respiration of partly dried plant organs, Smith.....	824
Physiological studies on the maturation of seeds, Ivanov.....	824
The formation of auximones from nitrogenous organic substances, Bottomley..	825
Location of spore masses in Uredineæ and value in classification, Grebelsky..	825
Succession and ecology of epiphytic bryophytes in Denmark, Olsen.....	825
Inheritance of eye pattern in beans and its relation to type of vine, Surface...	826
Factors influencing the weight of the bean seed, II, Harris.....	826
Selective partial sterility in double-throwing stock and petunia, Saunders...	826
Application of the pure-line concept to bacteria, Cole and Wright.....	826
Nitrocultures and their commercial application, Harrison.....	827

## FIELD CROPS.

Contributions to agronomic terminology, II-IV, Ball and Piper.....	827
Relative precision of formulas for calculating normal plat yields, Stockberger..	827
The root systems of agricultural plants, Miller.....	827
[Work with field crops in 1916].....	827
Experiments with farm crops, App.....	829
[Field crops work on county farms in Ohio in 1915], Montgomery et al.....	829
Report of the Bugyi experimental plat for the year 1914-15, Thompstone.....	830
Experiments with spring cereals at Moro, Oreg., Stephens.....	830
Seeding winter grains in furrows to prevent winterkilling, Salmon.....	831
The effect of clipping on the root development of alfalfa, McKee.....	832
Corn.—Varieties and limiting factor tests, season 1916, Hutchinson.....	832
Corn, yields per acre and prices, by States, 50 years, 1866-1915.....	832
Cotton.—Varieties and limiting factor tests, 1916, Hutchinson.....	832
Report on the manuring of mangels, Porter and McWilliam.....	833
A classification of the varieties of cultivated oats, Etheridge.....	833
Studies on oat breeding, III, Surface.....	834
Irish potatoes in Florida, Spencer.....	835
Yield and nitrogen of soy beans as affected by inoculation, Lipman and Blair..	835
Composition of sugar beets at various stages of the season, Zitkowski et al.....	835
Sugar-cane culture for sirup production in the United States, Yoder.....	835
Effect of rate and date of sowing on yield of winter wheat, Jardine.....	835
Wheat, yields per acre and prices, by States, 50 years, 1866-1915.....	836
Table for converting weights of separations into percentages, Boerner.....	836
Report of the department of seed analysis, Helyar.....	836
An alien weed.....	836

## HORTICULTURE.

[Report of horticultural investigations], Blake and Connors.....	837
[Report of heredity investigations], Halsted.....	838
Inheritance studies in garden plants, Owen.....	838
Truck crops, Green and Riggs.....	839
A chemical study of the asparagus plant, Morse.....	839
Connecticut Valley onion supply and distribution, Cance et al.....	840

	Page.
Root hardness of fruit trees.....	840
The cost of producing apples in western Colorado, Thomson and Miller.....	841
The cost of producing apples in Hood River Valley, Thomson and Miller.....	841
The mulched-basin system of irrigated citrus culture, Briggs et al.....	841
The mulch-basin system, Briggs, Jensen, and McLane.....	842
A humidifier for lemon-curing rooms, Shamel.....	842
Shade trees, characteristics, adaptation, diseases, and care, Stone.....	842
Fumigation of greenhouse plants with hydrocyanic acid, Sasser and Borden..	842

## FORESTRY.

A forest census of Alabama by geographical divisions, Harper.....	843
Thirteenth annual report of the State forester [of Massachusetts], Rane.....	843
The present and future of Pennsylvania's forests, Elliott.....	843
Tree planting on agricultural estates and roads, Brown.....	843
The Central Provinces forest manual.....	843
The relation between forests and atmospheric and soil moisture in India, Hill..	843
Seed selection in the cultivation of <i>Hevea brasiliensis</i> , Beadle and Stevens...	843
Ecology of sal.—III, Soil aeration and water cultures, Hole and Singh.....	844
Our wattles, Wollaston.....	844
Investigations of the rotting of slash in Arkansas, Long.....	844
Yields from the destructive distillation of certain hardwoods, II, Palmer.....	844
Poles purchased, 1915, McCreight.....	844
Handbook on wood preservation.....	844

## DISEASES OF PLANTS.

Transmission of diseases by seeds, Blaringhem.....	844
Chemotropic reactions in <i>Rhizopus nigricans</i> , Graves.....	845
Discovery of internal telia produced by a species of <i>Cronartium</i> , Colley.....	845
Discussion of certain plant diseases, Barrett.....	845
Report of the department of plant pathology, Cook et al.....	845
[Investigations on plant diseases].....	845
[Plant diseases in British Guiana], Bancroft.....	846
[Plant diseases in Tasmania], Nicholls.....	846
A physiological study of two strains of <i>Fusarium</i> , Link.....	846
The part played by the seed in the dissemination of potato diseases, Quanjer..	847
Nature, dissemination, and control of phloëm necrosis, Quanjer et al.....	847
Report of potato spraying experiments for 1915, Lint.....	847
Report of the potato scab experiments, 1915, Lint.....	848
Physiological studies of <i>Bacillus radicum</i> of soy bean, Wilson.....	848
A squash disease caused by <i>Choanephora cucurbitarium</i> , Wolf.....	848
Arsenical injury through the bark of fruit trees, Swingle and Morris.....	849
Diseases of deciduous fruit trees, Smith.....	849
Peach yellows and little peach at Vineland, Blake and Connors.....	849
Plum pockets, Rabaté.....	849
Little leaf of the vine, Bioletti and Bonnet.....	849
Control of <i>Oidium</i> or vine mildew, Bioletti.....	850
Spraying pineapple plants on manganese soils with iron sulphate, Johnson.....	850
Citrus canker investigations at the Singalong Experiment Station, Doryland...	850
Notes on the citrus canker, Wester.....	851
Diseases of the lime tree, Harrison, Bancroft, and Bodkin.....	851
A Phoma disease of lavender, Brierley.....	851
The extension of <i>Marsonia rosæ</i> on rose bushes, Chiffot.....	851
<i>Roesleria pallida</i> , Bayliss-Elliott and Grove.....	851
[ <i>Hevea</i> dieback in Sumatra], Vriens.....	852

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

A history of British mammals, Barrett-Hamilton and Hinton.....	852
Gopher destruction, Grisdale.....	852
The control of voles in Italy, Splendore.....	852
Destruction of oysters by crabs, Nelson.....	853
Insect enemies, Ealand.....	853
Mushroom pests and how to control them, Popeneo.....	853

	Page.
Pests of sugar cane in British Guiana, Hutson.....	853
General report on insect pests for the year 1915, Moore.....	853
Some new or little-known enemies of fruit trees, Kemner.....	853
Insects injurious to pine and fir trees in Sweden, Trägårdh.....	853
Measures against flies, mosquitoes, lice, and other vermin, Maxwell-Lefroy....	853
Twenty-ninth report of the State entomologist of Illinois, Forbes.....	853
Entomological report for 1915, Cory.....	854
Report of the department of entomology, Headlee.....	854
[Entomological investigations].....	855
Thirty-first report of the State entomologist of New York, 1915, Felt.....	855
[Report of entomological investigations].....	856
Notes on early stages and life history of the earwig, Chapman.....	857
Combating <i>Schistocerca peregrina</i> in Morocco in 1916 by biological method, Velu.	857
<i>Calocoris angustatus</i> , Ballard.....	857
The rose leaf hopper ( <i>Typhlocyba rosæ</i> ) and a new egg parasite, Tullgren.....	857
Solubility of the scale of <i>Lepidosaphes ulmi</i> , Maulik.....	857
Machine for treatment of cotton seed against pink bollworm, Storey.....	857
Peach borer observations at Vineland, Blake and Connors.....	857
A codling moth trap, Siegler.....	858
The effect of cold upon malaria parasites in the mosquito host, King.....	858
Report on mosquito work for 1915, Headlee.....	858
Biology of two tachinids which have an intramuscular stage, Thompson.....	858
<i>Sarcophaga froggatti</i> , n. sp.—A new sheep maggot fly, Taylor.....	858
On the life history and structure of <i>Telephorus lituratus</i> , Payne.....	858
Notes on the 12-spotted cucumber beetle, Sell.....	859
The rose flea-beetle ( <i>Haltica probata</i> ), Moznette.....	859
<i>Otiorynchus sulcatus</i> , an enemy of pot plants, Kemner.....	859
The leaf weevil ( <i>Polydrusus inpressifrons</i> ) in New York, Parrott and Glasgow..	859
Notes on the control of the white pine weevil, Graham.....	859
An Indian ant introduced into the United States, Wheeler.....	859
Two new genera of North American Entedoninae (chalcid flies), Girault.....	859
The privet mite in the South, McGregor.....	859
The life history and habits of <i>Tychius 5-punctatus</i> , Grandi.....	860

## FOODS—HUMAN NUTRITION.

Digestibility of some vegetable fats, Langworthy and Holmes.....	860
Studies on the digestibility of some animal fats, Langworthy and Holmes....	860
The solidity of oysters, Nelson.....	861
Copper content of green oysters, Nelson.....	861
General statistics of the [Alaska] fisheries in 1915, Bower and Aller.....	862
Some new constituents of milk.—II, The phosphatids, Osborne and Wakeman..	862
Milk: A cheap food, Rose.....	862
Colloidal swelling of wheat gluten and milling and baking, Upson and Calvin..	862
Turnips, beets, and other succulent roots, and their use as food, Langworthy...	863
The nutritional value of the banana, Myers and Rose.....	863
[Germicidal effect of spices].....	863
Nutritive value of agar agar and its use as a jellifying medium, Fellers.....	864
A study of American beers and ales, Tolman and Riley.....	864
The vitamin content of brewers' yeast, Seidell.....	864
[Food and drug inspection].....	864

## RECENT WORK IN AGRICULTURAL SCIENCE.

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Work of the chemical and yeast culture laboratory, W. SEIFERT ET AL. (*Programm u. Jahresber. K. K. Höh. Lehranst. Wein- u. Obstbau Klosterneuburg, 1912-13, pp. 103-155, fig. 1; 1913-14, pp. 106-157, pl. 1, figs. 2; 1914-15, pp. 76-89; 1915-16, pp. 84-115, fig. 1*).—These pages contain tabular analytical data relative to the total acidity, solids, total sugars, and invert sugar of the wines and musts handled at the institute from 1912 to 1916.

The report for 1912-13 also deals with the results of a study on the inversion and disappearance of tartaric acid, the determination of tartaric acid in the presence of citric acid, the advantage of using pure yeast cultures for fermentation of musts from partly fungus-diseased grapes, further tests on pure yeast fermentations, the refermentation of strong wines to an alcohol content of 13 per cent by volume, the action of pure nitrogen on musts and wine, the action of chloroform and mustard oil on the alcoholic fermentation of grape must, decolorization with "Eponite" and French decolorizing charcoals, and the results of tests of some mechanical appliances. That for 1913-14 contains the results of a study of wine and must concentration by freezing, the cooling and airing of young wine to accelerate its ripening, the formation of volatile acids during the fermentation of a sterile, a pasteurized, and an untreated apple juice, the formation of volatile acids during fermentation with juices of increasing sugar content, the effect of yeast on tartaric acid during fermentation, the adaptation of yeast to the presence of sulphurous acid, the influence of chloroform and mustard oil on the alcoholic fermentation of grape must, the action of sulphurous acid on the coloring substances in red wine, decolorization tests with certain commercial charcoals, the cleaning of casks which have stood unused for some time, and descriptions of a wine sampler and a pasteurizing apparatus. That for 1914-15 presents the results of a study on the adaptation of yeast to sulphurous acid and the use of pure yeast cultures for refermentations. That for 1915-16 includes the results of a study of the formation and disappearance of acetaldehyde in grape must during and immediately following fermentation, the preparation of vinegar from wine by Pasteur's method or the rapid procedure, the possibility of wine extracting sulphur dioxide from the wood of paraffined casks, partial neutralization of wines with calcium carbonate, conserving empty casks with alcohol and formaldehyde, rinsing of wine bottles with sulphurous acid, the removal of grape seeds from husks, the lowering of temperature to accelerate the ripening of the wine, and replacing the air of bottles with carbon dioxide before filling are reported.

On the presence of invertase in cane sugar, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 33 (1916), No. 10-12, pp. 263-266).—The author has observed that either a pure or impure solution of sucrose on standing for some time becomes inverted even in the presence of toluene. The inversion is greatest in the pure solution. If the sucrose solution is previously boiled no inversion takes place. The maximum temperature for the action was found to be from 55 to 57° C.

To prevent such loss during the process of cane sugar manufacture the use of concentrated solutions, rapid heating to a temperature of from 90 to 100°, or the use of alkali and a lower temperature to destroy the invertase are recommended.

See also a previous note by Lewton-Brain and Deerr (*E. S. R.*, 21, p. 420).

The autolysis of grapes, E. PANTANELLI (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 10-11, pp. 783-821, figs. 3).—Having found in earlier experiments that the must of ripe or overripe grapes contains a protease, the action of which appears to increase when the grapes are dried in the air, further experiments were conducted on the autolysis of the protein of the normally ripened grape and the decomposition of the carbohydrates under aerobic and anaerobic conditions.

It was found that there was an autolysis of the albumin and a decomposition of the sugars and acids to a limited degree in ripe grapes (removed from the plant and kept whole) when exposed to the air, and to a greater extent when immersed in sterile water. It is concluded that under anaerobic conditions the mature grape forms alcohol by intracellular respiration of the sugar without the intervention of alcoholic ferments.

A study of the yeasts of wine, E. KAYSER (*Rev. Vit.*, 45 (1916), Nos. 1158, pp. 149-155; 1159, pp. 165-170).—This is a general discussion of experimental data submitted in tabular form. The effect on the finished product of the kind of yeast used and the amount of nitrogenous and mineral constituents present in the fermentation is emphasized.

The relative influence of microorganisms and plant enzymes on the fermentation of corn silage, A. R. LAMB (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 10, pp. 361-380, figs. 13).—The author at the Iowa Experiment Station briefly reviews the literature on silage fermentation and emphasizes the difficulty encountered in an attempt to differentiate between the activity of microorganisms and plant cell enzymes in the process of fermentation. Experimental data on silage made under antiseptic conditions, the rate of chemical changes in the silage fermentation, the evolution of carbon dioxide, and the rise in temperature are reported and discussed.

It is concluded from the data that neither microorganisms nor plant enzymes are alone responsible for the changes which take place in corn silage fermentation. Bacteria appeared to be mainly responsible for acid production and the concomitant disappearance of sugars. The formation of alcohol appears, however, to be a phenomenon primarily of the respiratory or enzymatic activity of the plant cells, and later to be carried on by the yeasts. Protein is hydrolyzed first by enzymes and later by microorganisms. The microorganisms are deemed probably largely responsible for the heating of the silage.

A bibliography of 27 references to the literature is appended.

Cytological researches in the fermentation of a fruit "compound," NATALINA DONNA (*Ann. R. Accad. Agr. Torino*, 58 (1915), pp. 334-340).—This article discusses the changes in the plasma and nuclei of the cell during fermentation, changes in the nitrogenous substances, and modifications of the structure of the parenchyma.

Plant oils, I, II, S. L. IVANOV (*Soobshch. Biuro Chastn. Rast. [Petrograd]*, 2 (1915), Nos. 1, pp. 3-22; 7, pp. 39-45).—From analytical data reported in the

first of these papers, the author concludes that each closely related group of plants develops a distinct and characteristic oil content which is peculiar to every species of a given genus. The results are considered to be significant not only for the systematic botanist, since they render a physiological criterion for natural classification of higher and lower forms, but also have a practical value in regard to the propagation and culture for industrial purposes of plants which have been neglected in the past.

It is noted in the case of *Spergula arvensis* that the seed oil undergoes a marked physiological and chemical change during the storage period, forming a coating impermeable to water and so retarding germination.

Analytical data of certain yeasts, Chlorophyceæ, Gymnospermæ, and several species of *Juglans* and *Linum* are submitted.

In work reported in the second paper he found that the composition of the walnut oils from different localities of Europe and Asia remained constant. Sunflower seed collected in two different Provinces, Kharkof and Voronezh, showed no essential difference. The oil of *Hyoscyamus niger* was found to be formed gradually, and the oil of the immature seeds differed from that of the ripe seeds.

Chemical composition of certain ethereal oils of Russian origin, G. V. FIGULEVSKĪĭ (*Soobshch. Būro Chastn. Rast. [Petrograd], 3 (1916), No. 3, pp. 3-16*).—The oils were analyzed of *Ruta graveolens*, *Rosmarinus officinalis*, *Ocimum basilicum*, *Laurus nobilis*, *Hyssopus officinalis*, *Salvia grandiflora*, and *Lavandula spica*, and the data submitted. It was found that the Crimean ethereal oils do not differ essentially from the imported oils. It is indicated that the vast natural resources and favorable climatic conditions of Russia will greatly stimulate the development of the oil industry in that country.

Some new oil seeds derived from American palms, G. T. BRAY and F. L. ELLIOTT (*Analyst, 41 (1916), No. 487, pp. 298-302*).—Tabulated analytical data of the composition of the kernels as regards moisture and oil content and the physical and chemical constants of the oils obtained from a number of seeds of South American and West Indian palms are submitted. The seeds were, on the whole, found to be as rich as or richer than those of ordinary West African palms.

Notes on the oils obtained and the press cake of the kernels are included.

Plum oil and its relation to other oils of the genus *Prunus*, S. L. IVANOV (*Soobshch. Būro Chastn. Rast. [Petrograd], 2 (1915), No. 7, pp. 46-55*).—The author finds no essential difference in the composition of the oils from various species of *Prunus*. The simplest oil of this genus is considered to be that of the domestic plum (*Prunus domestica*). Apricot seeds give at least 25 per cent of oil.

Methods used in the analyses are described in detail.

Physiological characters of plants and botanical families.—I, Malvaceæ.—Oil and fiber, S. L. IVANOV and N. F. KOKOTKINA (*Soobshch. Būro Chastn. Rast. [Petrograd], 2 (1915), No. 7, pp. 3-24*).—The results of the investigation reported are as follows:

There are many valuable species of Malvaceæ which as yet are not used commercially, such as *Lavatera thuringiaca*, Malva, and other fiber species. The oils of the 30 species of Malvaceæ which were studied do not differ essentially from cottonseed oil. The oils of the Malvaceæ and those of the nearest forms of the Tiliaceæ are both characterized by Halphen's reaction, which indicates the presence of a peculiar unsaturated acid in these groups. The presence and the formation of this acid unites these two families as their common physiological character.

The hairs of the seed coating of some of the other species of Malvaceæ are considered to be very similar to cotton fiber. The possibility of successful crossings between *Gossypium* and other Malvaceæ is suggested.

Data concerning the character of seeds of different varieties of cotton, S. L. IVANOV and E. I. MOSHKOVA (*Soobshch. Bûuro Chastn. Rast. [Petrograd], 2 (1915), No. 4, pp. 3-35*).—From an investigation of several species and varieties of *Gossypium*, arranged by the Russian Ministry of Agriculture with regard to the cotton industry in Russian central Asia, it was found that, considering the quality of seeds from the standpoint of oil content and press cake and the quality of fiber, *Gossypium hirsutum* has a much greater practical value than any other variety studied. It is indicated that the cultural area of *G. hirsutum* is gradually extending, while that of *G. herbaceum* is gradually diminishing.

Tables giving detailed analytical results of a number of cotton seeds are appended.

Globulin obtained from seeds of *Gossypium hirsutum*, A. POMASKÏĪ (*Soobshch. Bûuro Chastn. Rast. [Petrograd], 2 (1915), No. 2, pp. 3-12*).—The author finds that globulin is the chief constituent of the protein substances of the cotton seeds. The globulin of *G. herbaceum* and that of *G. hirsutum* are probably identical. The proteins of the cotton seed are considered to be highly digestible, the coefficient of digestibility with the gastric juice of the dog being found to be from 99 to 100 per cent. The value of the press cake as a feeding stuff is indicated.

Leucin anhydrid, a product of the water hydrolysis of protein at high temperatures, S. S. GRAVES, J. T. W. MARSHALL, and H. W. ECKWEILER (*Jour. Amer. Chem. Soc., 39 (1917), No. 1, pp. 112-114*).—The following percentages of leucin anhydrid were extracted with ether from the brown, sirupy liquid resulting from hydrolysis with water in an autoclave at from 180 to 200° C. for 16 hours: Casein, 1.5; egg albumin, 1.2; edestin, 1.2; Witte's peptone, 1; silk, 0.09; gelatin, 0.04. The material extracted by the ether was purified by recrystallization from hot acetone. An experiment to determine the source of the leucin anhydrid is reported and indicates that the anhydrid is not built from any leucin separated by the hydrolysis.

An iodine addition product of cumarin, A. W. DOX and W. G. GAESSLER (*Jour. Amer. Chem. Soc., 39 (1917), No. 1, pp. 114-117*).—The authors at the Iowa Experiment Station describe the preparation of an iodine addition product of cumarin containing approximately 33 per cent of iodine. Analysis of the product showed that no substitution by the iodine occurred.

Carbon monoxid, occurrence free in kelp (*Nereocystis luetkeana*), S. C. LANGDON (*Jour. Amer. Chem. Soc., 39 (1917), No. 1, pp. 149-156, figs. 3*).—Experimental data are reported which show that the gas in the giant kelp (*N. luetkeana*) contains carbon monoxid in quantities varying considerably in different samples. Carbon dioxide is only occasionally present, and in minute quantities. Previous work which demonstrated that the quantities of carbon dioxide and oxygen varied with the time of day has not been confirmed.

Ancient Irish oak, P. A. E. RICHARDS (*Analyst, 41 (1916), No. 487 pp. 303, 304*).—Data relative to the general composition and mineral constituents of a number of Irish oaks taken from various districts are submitted.

Photomicrographs of crystallizable chemical salts, A. W. DOUBLEDAY (*Boston: Research Publishing Co., 1916, pp. V+236, figs. 115*).—This volume contains 114 photomicrographs of typical crystalline forms of various chemical compounds known to exist in the body tissues and fluids under normal and pathological conditions. Brief notes on crystallization and a description of the six crystal systems are included.

Some laboratory conveniences, A. E. PERKINS (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 57, 58, figs. 4).—The author, at the Ohio Experiment Station, describes a special flat-bottomed Kjeldahl flask for use with the extraction apparatus previously described<sup>1</sup>; a convenient, satisfactory, and easily assembled burette support; two convenient pipettes for sampling milk and milk products; and a novel and convenient drying rack for laboratory glassware.

Carbon dioxid absorption apparatus, L. G. WESSON (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, p. 59, fig. 1).—A simple apparatus consisting of a cylindrical bulb for carbon dioxid absorption with soda lime and a smaller arm attachment to contain the drying agent is described.

Apparatus for the recovery of bromin, C. H. COLLINGS (*Chem. News*, 114 (1916), No. 2975, pp. 259, 260, fig. 1).—An apparatus for the recovery of bromin from laboratory waste liquors and its manipulation are described in detail.

Note on the recovery of molybdic acid, P. RUDNICK and R. D. COOKE (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 109, 110).—The procedure, which is similar to that described by Brown<sup>2</sup>, is as follows:

The phosphomolybdate solutions, after titration, are filtered through glass wool and combined with the filtrates and washings separated from the yellow precipitates. To this, an excess of saturated ammonium phosphate is added and after standing at least over night the supernatant liquid is siphoned off. When a convenient amount of ammonium phosphomolybdate has been collected in this manner it is washed by decantation with hot water and then dried on the steam bath. This material contains approximately 92 per cent of molybdic acid (85 per cent  $\text{MoO}_3$ ). Of this dried salt 510 gm. is dissolved in ammonium hydroxid, made by diluting 620 cc. of ammonia (specific gravity 0.9) to 1,000 cc. To this, 85 gm. of magnesium nitrate in 200 cc. of water is added and after settling for two or three hours the filtrate is tested for phosphorus by adding a few cubic centimeters to double the amount of nitric acid (1:2.5). When precipitation is complete the magnesium-ammonium phosphate is filtered off, washed, and the filtrate made up to a volume of 2 liters. The ammonium molybdate solution is then added to the requisite amount of nitric acid and, after standing for some time, filtered.

Notes in regard to titration of sulphuric acid, C. R. GYZANDER (*Chem. News*, 114 (1916), No. 2975, pp. 260, 261).—Analytical data showing the error that is likely to be introduced when an alkali is standardized with one indicator and then used for acid titrations with a different indicator are submitted and discussed.

Handling a standard solution of barium hydrate, W. G. HAYNES (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 58, 59, fig. 1).—An easily constructed attachment to the usual siphon arrangement used in filling burettes with standard barium hydroxid solutions and its manipulation are described in detail.

The use of the Cottrell precipitator in recovering the phosphoric acid evolved in the volatilization method of treating phosphate rock, W. H. ROSS, J. N. CAROTHERS, and A. R. MERZ (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 26–31, fig. 1).—The authors have applied the Cottrell precipitator in recovering the phosphoric acid evolved in the volatilization method of treating phosphate rock by ignition with coke and silica in an electric furnace. The new method is claimed to possess a number of advantages over the scrubbing-tower method now in use.

<sup>1</sup> *Jour. Indus. and Engin. Chem.*, 5 (1913), No. 2, pp. 148, 149.

<sup>2</sup> *Jour. Indus. and Engin. Chem.*, 7 (1915), No. 3, pp. 213, 214.

It is pointed out that the present application of the Cottrell precipitator is the first to be used for the precipitation of a product which has been purposely volatilized with a view to its recovery in this way.

The determination of total phosphorus in bone ash, F. PILZ (*Ztschr. Landw. Versuchsw. Österr.*, 19 (1916), No. 2, pp. 57-61).—Comparative analytical data show that as accurate results can be obtained when the sample is oxidized with a mixture of sulphuric and nitric acids as when nitric acid alone is used. The preliminary precipitation as ammonium phosphomolybdate is considered not to be absolutely necessary for reliable results. These modifications are deemed to be of some importance in view of the scarcity and high price of the chemicals necessary in these operations.

A colorimetric method for the determination of the  $\text{CO}_2$  percentage in air, H. L. HIGGINS and W. MCK. MARRIOTT (*Jour. Amer. Chem. Soc.*, 39 (1917), No. 1, pp. 68-71).—A method which depends on determining the reaction of a solution of sodium bicarbonate after passage of air until the solution is saturated with carbon dioxide is described in detail. The reaction of such a solution will depend on the relative amounts of the alkaline bicarbonate and carbonic acid present. This in turn depends on the pressure of the carbon dioxide in the air with which the mixture has been saturated and is independent of the volume of air passed through the liquid. High pressures of carbon dioxide change the reaction of the solution toward the acid side, while low pressures have the reverse effect.

The indicator used is phenolsulphonophthalein and the standards, acid potassium phosphate ( $\text{KH}_2\text{PO}_4$ ) and alkaline sodium phosphate ( $\text{Na}_2\text{HPO}_4$ ).

The method is not applicable in the presence of acid or ammonia fumes.

On the determination of small amounts of arsenic with special reference to the procedure according to Smith, K. BECK and MERRES (*Arb. K. Gsndhtsamt.*, 50 (1915), No. 1, pp. 38-49, pls. 2, figs. 2).—This is a general review and discussion of the methods proposed for the determination of minute quantities of arsenic.

The method described by Smith (E. S. R., 28, p. 24) is deemed very satisfactory and to yield very accurate results, especially in the examination of foods and food products. The procedure is easy to manipulate and requires a minimum of time and only a very small sample, this being an especially great advantage with organic material.

It is indicated that the simple colorimetric method is accurate for differentiating amounts of arsenic of 0.002, 0.005, 0.01, 0.02, 0.03, and 0.04 mg. For greater accuracy the procedure should be used only as an indicator, the ultimate determination being made either gravimetrically or titrimetrically, preferably the latter.

Some analytical data of the arsenic determined in various meat, plant, and yeast extracts, caviar, hydrogenated oils, and gelatin are submitted.

A new procedure for the determination of methyl alcohol in the presence of ethyl alcohol, G. REIF (*Arb. K. Gsndhtsamt.*, 50 (1915), No. 1, pp. 50-56).—A procedure which depends on the formation of trimethylsulphiniodid and subsequent titration with silver nitrate and retitration with ammonium thiocyanate is described in detail, as well as a slightly modified procedure for determining methyl alcohol in brandy in which the acids, esters, aldehydes, and acetone usually present do not interfere. Analytical data submitted indicate the accuracy of the procedure.

The determination of raffinose in the presence of sucrose by means of double inversion with two special yeasts, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 33 (1916), No. 10-12, pp. 255-262).—The unreliability of the usual procedure of polarization before and after inversion with acid in the

presence of appreciable amounts of nitrogenous reducing substances (glutamin and asparagin) is pointed out. The newer methods of inversion by double fermentation with "top" and "bottom" yeast are considered to yield excellent results and to be entirely reliable. Some analytical data are submitted.

The estimation of pentose or pentosans by means of Fehling's solution, J. L. BAKER and H. F. E. HULTON (*Analyst*, 41 (1916), No. 487, pp. 294-297).—The authors have used the method of Flohrl as improved by Eynon and Lane (E. S. R., 27, p. 113), and indicate as decided improvements in the procedure the use of a much larger volume of Fehling's solution, in order that a considerably larger fraction of the total distillate may be treated, thus increasing the weight of CuO obtained, and, instead of boiling the solution, heating by immersion in a boiling water bath.

The values for the CuO equivalent of pure furfural found by Eynon and Lane were confirmed. The figures for the CuO yielded from 20 cc. of Fehling's solution with sodium chlorid alone were not in agreement. This discrepancy in results, as well as the procedure in general, is briefly discussed.

Determination of sugar in hay and turnips, R. K. KRISTENSEN (*Tidsskr. Planteavl*, 23 (1916), No. 2, pp. 233-250).—Detailed tabular analytical data of the sugar content of hay and turnips are submitted. From the data it is concluded that the use of lead acetate with Fehling's solution for the determination of sugar introduces errors in the results.

Control analyses were made with a solution of pure sucrose.

The determination of fat in cacao products, W. LANGE (*Arb. K. Gsndhtsamst.*, 50 (1915), No. 1, pp. 149-157, fig. 1).—The author discusses the incomplete extraction of cacao fat obtained with a Soxhlet apparatus, and describes a new procedure for the determination. The procedure consists of extracting the sample on a Witte plate with an asbestos filter by suction with small portions of ether. The ether is then evaporated and the fat weighed in the usual manner. The procedure requires considerably less time than the older method of extraction and is deemed to be as satisfactory in every respect.

Some experimental data are submitted.

The alcohol test in milk, I. M. KOLTHOFF (*Pharm. Weekbl.*, 53 (1916), No. 47, pp. 1589-1600).—The alcohol test in milk is considered to depend on the calcium ions present. In normal milk the alcohol test (with 70 per cent alcohol) appears when the acidity is equivalent to 7.8. In abnormal milk there is no relation between the alcohol test and the acidity, but the test also appears here with a comparatively low acidity.

For the practical examination of milk, as well as from a hygienic and pathological-chemical standpoint, the test is considered to be of great importance. If no flocculation appears the double test (using twice the amount of alcohol) should be used. Flocculation in a sample of normal acidity probably indicates an abnormal milk. As a check on the result the catalase index and leucocyte content should be determined.

The detection of added water in milk, H. DURAND (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 44, 45).—This is a brief review of the methods which have been proposed for determining added water, namely, by the refractive index of the serum, the freezing point of the whole milk, and the specific gravity of the whole milk and serum. Some experimental data on the freezing point method are included and discussed.

The action of various animal charcoals on pure and impure sugar solutions and their influence in the analysis of sugar refinery products, H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill.*, 33 (1916), No. 10-12, pp. 220-227).—The results of experiments in which a number of charcoals were used in the

analysis of sugar products show that different samples vary greatly in density and composition. A great variation in their decolorizing power was also observed. A variable amount of sugar was absorbed by the samples, the absorption being much less in the presence of lead. In a solution of molasses defecated with lead subacetate there was no appreciable absorption of sugar. In a complete analysis of a molasses solution some samples of charcoal gave slightly low results, while others did not appreciably affect the results. Special decolorizing charcoals were found not to absorb the reducing substances in beet or cane-sugar molasses, but did absorb some nonfermentable, polarizable material in the cane molasses.

The experimental data are submitted in tabular form.

The occurrence and determination of citric acid in wine, F. WOHACK (*Ztschr. Landw. Versuchsw. Österr.*, 19 (1916), No. 2, pp. 53-56).—The author considers that citric acid may occur as a normal constituent in wine.

Of the methods proposed for the determination of citric acid the procedure of Kunz<sup>1</sup> is considered to be the most reliable.

The identification and estimation of lactic acid in biological products.—First paper, I. K. PHELPS and H. E. PALMER (*Jour. Amer. Chem. Soc.*, 39 (1917), No. 1, pp. 136-149, fig. 1).—Experimental data are submitted which show that lactic acid may be estimated as the guanidin salt and identified by its melting point after separation by esterification from citric and tartaric acids and by fractional distillation from formic and acetic acids. It may be separated from mixtures containing formic, acetic, propionic, butyric, and citric acids and accurately estimated by weighing as quinln lactate, which may be identified by its melting point.

“The separation from citric acid and other acids whose ethyl esters also have high boiling points is effected by esterification with the vapor of alcohol containing dry hydrochloric acid gas in solution, passed through the mixture suspended in vaselin at a temperature of 100 to 110° [C.], using zinc chlorid as a second catalyzer; the ethyl lactate passes quantitatively into the distillate, while the ethyl citrate remains in the flask. By fractional distillation of the distillate through a Hempel fractionating column filled with glass beads the ethyl formate and ethyl acetate, together with a large part of the ethyl propionate and ethyl butyrate, are removed. The residue in the flask, containing the ethyl lactate, is hydrolyzed and converted to the quinln salts, and the quinln lactate is separated from the propionate and butyrate by the solubility of the quinln salts of the latter in carbon tetrachlorid. The quinln lactate may then be weighed and identified by its melting point.”

Rate of turbidity in beverages containing maltose, glucose, or maltose and glucose, A. W. HOMBERGER and C. S. MARVEL (*Jour. Amer. Chem. Soc.*, 39 (1917), No. 1, pp. 156-162).—From the study reported it is concluded that turbidity may occur in solutions containing glucose without the presence of albuminous or mineral constituents. The turbidity is due to germination of the spores of the mold *Penicillium glaucum* in the glucose medium. The presence of alcohol and carbon dioxid has no appreciable effect on the appearance of the turbidity in glucose solutions. Maltose does not act as a chemical stimulus on the spores and hence maltose solutions do not become turbid on standing.

The concentration of lime juice by freezing (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica, 1915-16, pp. 33-36*).—Following the procedure outlined by Gore (E. S. R., 33, p. 209), experiments are reported from which it is concluded that raw lime juice can be concentrated by freezing and centrifugalization without affecting its properties as a beverage. By one treatment the acid

<sup>1</sup> *Ztschr. Untersuch. Nahr. u. Genussmtl.*, 2 (1899), No. 9, pp. 692-694.

content of the juice may be increased from about 13 oz. to over 20 oz. per gallon. If this concentrated juice be again treated a juice containing 30 oz. per gallon can be obtained. The low testing juices can be converted into calcium citrate, thus eliminating all losses. The economic importance of the process with respect to package and transportation charges is indicated.

The utilization of olive pomace, W. V. CRUESS and A. W. CHRISTIE (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 45-47).—The authors at the California Experiment Station have found from 7.89 to 20.23 per cent of oil in fresh pomace (equivalent to from 20.98 to 53.81 gal. per ton). The most satisfactory solvent for the recovery of the oil from the air-dried pomace was found to be gasoline, and four extractions were sufficient. The air-dried pomace of lowest oil content was found to yield 25.5 gal. of oil per ton by gasoline extraction. The composition of the oils extracted with gasoline, benzol, and ligroin compared favorably with that of pure olive oil in regard to their value for soap making. Distillation by direct heat was found to be the most satisfactory procedure in the recovery of the solvent. It is indicated that "no commercial value as fertilizer should be assigned to olive pomace, either before or after extraction."

The utilization of *Imperata cylindrica* P. B. in the paper industry, F. VIGNOLO-LUTATI (*Ann. R. Accad. Agr. Torino*, 58 (1915), pp. 69-76).—Results of the study reported show that the grass *I. cylindrica* yields a very satisfactory cellulose fiber, about 38 per cent of the raw material being converted into bleached fiber. In the use of the stock a smaller quantity is necessary for the production of the finished product than with some other grasses.

The removal of barium from brines used in the manufacture of salt, W. W. SKINNER and W. F. BAUGHMAN (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 1, pp. 18-26, fig. 1).

The theory of drying and its application to the new humidity-regulated and recirculating dry kiln, H. D. TIEMANN (*U. S. Dept. Agr. Bul.* 509 (1917), pp. 28, figs. 3).—This discusses the subject with special reference to the drying of lumber, under the topics of elementary principles of drying, elementary principles of hygrometry, types of kilns, drying by superheated steam, importance of proper piling of lumber, theory and description of the U. S. Forest Service kiln, theoretical discussion of evaporation, theoretical analysis of heat quantities, and increase in density produced by evaporation.

## METEOROLOGY.

A preliminary study of climatic conditions in Maryland, as related to plant growth, F. T. McLEAN (*Physiol. Researches*, 2 (1917), No. 4, pp. 129-208, figs. 14).—This is a detailed account of studies briefly and partly reported upon elsewhere (*E. S. R.*, 33, p. 116). Observations on the growth of soy bean seedlings on the same soil uniformly supplied with moisture at Easton, on the Eastern Shore of Maryland, and at Oakland, in the mountains of western Maryland, are reported and discussed.

Plantings were made in plunged pots every two weeks during the growing season and the plants were allowed to grow for a month. The soil was kept uniformly moist by means of autoirrigators. Evaporation was measured by means of standardized cylindrical porous-cup atmometers. Daily, maximum, and minimum temperatures were observed in the usual manner and account was also taken of sunshine records, rainfall, and soil moisture. After two weeks' growth measurements were made of "stem height, average number of leaves per plant, average length and width of mature leaves, and average of the products obtained by multiplying length by width for each leaf. After

about a month of growth these measurements were repeated and, also, the average leaf area and the average dry weight of tops per plant were determined."

It was found that the conditions at Easton were more favorable for the growth of soy-bean plants than those at Oakland. "The total efficiency of the Easton frostless season for 1914, measured in terms of leaf-product as here used, was about 2.5 times as great as that of the Oakland frostless season." Stem height, leaf surface, and dry weight furnished the best means of comparison of the growth rates of the experimental plants. "The rates of growth in stem height were generally more rapid during the first than during the second fortnight of growth from the seed, for both stations. On the other hand, the rates of increase in leaf area (as approximately measured by means of the leaf-product) were generally more rapid during the second fortnight."

The growth rates generally showed very evident seasonal marches which were most clearly shown by the rate of increase in stem height and corresponded in general trend to the seasonal marches of the temperature conditions. "The seasonal marches of both the growth rates and the temperature values for Oakland are quite markedly different from those for Easton. Both ranges are greater for Easton than for Oakland. The highest temperature values and the highest growth rates occurred at Easton, and the growing season was terminated by killing frost earlier at Oakland than at Easton. Nevertheless, the last two-week period before autumn frost at Oakland exhibited a higher temperature value and higher growth rates than did the last two-week period before frost at Easton.

"This difference between the magnitudes of the final minimum growth rates observed at the two stations appears to emphasize one of the main differences between a mild, equable, coastal climate and a much more rigorous mountain climate, as these may influence plant growth. In the milder climate of Easton, with its small daily range of temperature, the frostless season is apt to be prolonged until the growth of many plants is much reduced or entirely checked by low temperature. In the mountain climate of Oakland, however, with its large daily range of temperature and high nocturnal radiation, very low night temperatures and frosts occur earlier in the season, while the day temperatures and the growth rates of many plants are still high. These differences between the two stations, as regards the temperatures and growth rates exhibited at the close of the season (just before autumn frost), are surely intimately associated with the two types of climate here illustrated, and are of undoubted importance in the consideration of plant life in general.

"Another difference to be noted between the two stations here considered refers to the time of occurrence, within the growing season, of the maxima of temperature and of growth rates. These maxima occurred about a month earlier at Oakland than at Easton—a fact that may be of significance in the comparative seasonal climatology of these stations, at least for the summer of 1914. . . .

"It appears that temperature was clearly the limiting condition (in the usual sense) for growth during the first two weeks, in practically all cases. During the second two weeks of growth, however, with exactly the same environmental conditions, the moisture relation (rainfall-evaporation ratio) appears in many cases to have been the limiting condition for growth, this being especially true . . . when the temperature was high. It thus appears that if two plants in different stages or phases of their development are exposed to the same fluctuations in environmental conditions, the limiting condition for one plant during a succeeding period may be of an entirely different nature from that for the

other. This must be due to a difference between the internal conditions of the plants at different developmental stages."

As a test of the methods employed the results indicated that many of the new methods proposed for work of this kind "are of value, and the data obtained by their means throw light upon the question of the influence and relative importance of several different climatic features, as these affected the growth of the culture plants." They indicated that culture plants may be successfully used as integrating instruments for the measurement of climate, that the autoirrigator furnishes a satisfactory means for soil moisture control, and that the standardized cylindrical porous-cup atmometer, taken with the ordinary precipitation records, gives a ratio of rainfall to evaporation that appears to be a very valuable measure of moisture conditions. Sunshine records obtained by the Marvin sunshine recorder were also found to be of some value.

Weather forecasting, G. S. BLISS (*U. S. Dept. Agr., Weather Bur. Bul. 42, 2. ed. (1917), pp. 37, figs. 4*).—In this second edition (*E. S. R., 29, p. 120*), "the style and subject matter have been alternated slightly to conform more closely to the uses to which the pamphlet has been put. The errors that crept into the first edition have been eliminated so far as possible, thus bringing it up to date and in accordance with our present knowledge of the subject."

Weather observations, A. J. FARLEY (*New Jersey Stat. Rpt. 1915, pp. 65, 66*).—Observations on temperature and precipitation at New Brunswick during 1915 are summarized. The maximum temperature, 92° F., was recorded July 31; the minimum, 2°, December 27. The total annual rainfall was 50.03 in., 1.31 in. above the normal.

[**British rainfall in 1916**], H. R. MILL (*Times [London], 1917, Jan. 25; rev. in Nature [London], 98 (1917), No. 2466, p. 435*).—Detailed results are given for 131 stations. These show that 1916 was generally a wet year in the British Isles, the rainfall being far in excess of the average at most stations and slightly below at a few. A deficiency of rainfall occurred in the extreme southwest of Wales and the northwest of Devon and Cornwall, and in two areas in the center of England. The area over which the year was relatively dry was much less than in any other of the last 12 years except 1912.

"The excess of rain was most pronounced in the south of England, the center of Scotland, and the southwest, northwest, and east of Ireland. The wettest part of England was in the district of East Grinstead, where the excess was about 40 per cent. In Scotland the excess of rainfall was 20 per cent over nearly one-half of the country, while in parts there was an excess of more than 40 per cent. The whole of Ireland was wet; the greatest excess of more than 30 per cent stretched inland from Dublin Bay. No year since 1903 has been wetter than last year in Scotland and Ireland, while the British Isles as a whole have only been wetter than 1916, during the last 50 years, in 1903, 1882, 1877, and 1872."

Results of rainfall observations in New South Wales, 1909–1914, H. A. HUNT ET AL. (*Melbourne: Govt., 1916, pp. 224, pls. 14, fig. 1*).—This is a continuation of a report published in 1909 bringing the rainfall history of New South Wales up to the end of 1914.

"The work, in addition to the general notes, includes tabular statements of rainfall at some 2,100 stations for the years 1909 to 1914, inclusive, and the annual averages computed from the commencement of the period over which the records extend; also rainfall notes and maps for each of the foregoing years; a statement and graphs showing the state of the rivers since the last report; a very carefully prepared table showing the yearly rainfall averages derived from selected stations in each of the divisions of the State, also the

State itself, and an explanatory graph of weighted results as far back as records available would permit; tables giving the monthly rain records at 167 specially selected stations with monthly and annual averages; also maps indicating the prevalence of frosts, hail, and rain during the wheat period, namely, April to October; and, finally, as an appendix, the results of meteorological observations taken at the Sydney observatory since 1840."

Summarizing the records of each district of New South Wales for a period of 44 years, 1871 to 1914, inclusive, it is shown that the average district rainfall varied from 11.44 in. in the southern portion of the western division to 50.2 in. in the north coast division, the former comprising about one-seventh of the whole area of the State. "As the country extends in an easterly and north-easterly direction the rainfall becomes greater, and finally reaches its highest district fall in the neighborhood of the north coast."

### SOILS—FERTILIZERS.

**Analyses of soils of Jones County, W. A. WORSHAM, JR., L. M. CARTER, D. D. LONG and M. W. LOWRY** (*Bul. Ga. State Col. Agr., No. 93 (1916), pp. 47, figs. 2*).—This is a report of chemical analyses of the soils of the county to supplement the physical survey of the soils made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture (E. S. R., 32, p. 513).

"Taking the average of all the soils of the county, the analyses show the plant food content to be as follows: Nitrogen 0.0265, phosphoric acid 0.0377, and potash 0.639 per cent." It is stated that while the soils of the county show a rather wide variation in plant food content, the nitrogen content is uniformly low in practically all of them and is the limiting factor of crop production.

**Soil survey of White County, Indiana, T. M. BUSHNELL and C. P. ERNI** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 43, fig. 1, map 1*).—This survey, made in cooperation with the Indiana State Department of Geology, deals with the soils of an area of 324,480 acres in northwestern Indiana, the topography of which is generally that of a level to gently undulating plain.

"The northern half of the county is an old lake plain characterized by black, formerly marshy, sandy lands and light sand ridges. The southern half is a glacial plain with low moraines, and includes both timbered and prairie lands. The county is now completely drained by systems of dredged and scraped ditches and by tiles."

Including muck, 17 soil types of eight series are mapped, of which the Brookston silt loam, Clyde fine sandy loam, Plainfield fine sand, and Clyde silty clay loam cover 19.8, 16.9, 14.2, and 10.6 per cent of the area, respectively.

**Soil survey of Newton County, Missouri, A. T. SWEET, E. S. VANATTA, and E. W. KNOBEL** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 41, pls. 3, figs. 2, map 1*).—This survey, made in cooperation with the Missouri Experiment Station, deals with the soils of an area of 398,080 acres in southwestern Missouri. "Approximately one-third of the county consists of almost level to gently rolling uplands, a considerable proportion is embraced in stream flood plains and terraces, and the remainder includes gently rolling to rough, hilly land."

The soils of the county are of residual and alluvial origin. Twelve soil types of 10 series are mapped, of which the Baxter gravelly loam, Lebanon silt loam, and Gerald silt loam cover 34.3, 19.3, and 10.9 per cent of the area, respectively.

Soil survey of Alleghany County, North Carolina, R. T. A. BURKE and H. D. LAMBERT (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 26, fig. 1, map 1*).—This survey, made in cooperation with the North Carolina Department of Agriculture, deals with the soils of an area of 133,760 acres in northwestern North Carolina which lies in the Appalachian Mountain and Plateau province. Mountainous topography prevails, but there are many rounded elevations of generally smooth surface. There is said to be little undrained land in the county.

The soils are of residual and alluvial origin. Including rough, stony land and rock outcrop, eight soil types of five series are mapped, of which the Ashe loam and Porters loam cover 51.4 and 25.3 per cent of the area, respectively.

Soil survey of Hampton County, South Carolina, M. W. BECK and A. L. GOODMAN (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 37, fig. 1, map 1*).—This survey deals with the soils of an area of 392,320 acres in southern South Carolina which lies wholly within the Coastal Plain province. The topography ranges from flat to gently rolling and rolling. Regional drainage is not well developed. The soils range in texture from coarse sand to clay. Including swamp, 21 soil types of 10 series are mapped, of which the Norfolk fine sandy loam and the Coxville fine sandy loam cover 13.6 and 11.3 per cent of the area, respectively. The Norfolk series covers about 40 per cent of the area.

[Soil studies at the Wisconsin Station] (*Wisconsin Sta. Bul. 275 (1917), pp. 18-24, figs. 2*).—Experimental work at the station on the management of different Wisconsin soils, soil drainage, and soil acidity is briefly reviewed.

[Soils], P. S. BURGESS (*Rpt. Expt. Sta. Com., Hawaii. Sugar Planters' Assoc., 1916, p. 13*).—Studies of old and new Hawaiian cane soils to determine the effect of continued cane culture on the chemical composition of the soil showed that "the older fields contain more readily available but less total plant food than the new lands. About 20 per cent of the total nitrogen and nearly 40 per cent of the total phosphoric acid have disappeared from the surface soils of the fields which have been cropped. . . . The bacterial activity in these soils was pronounced. Nitrification was better in the older fields. Gypsum and reverted phosphate stimulated nitrification but slightly."

Studies of acid soils of Hawaii showed that "ammonification is universally low and that nitrification, though slightly better, is also low. The addition of gypsum and reverted phosphate at the rate of 2 tons per acre increased the nitrification of dried blood by over 50 per cent. When just sufficient lime carbonate was added to neutralize exactly the soil acidity the ammonification and nitrification of dried blood was in many cases more than doubled, while in two instances this beneficial bacterial action was increased tenfold or more."

Combinations of soils in plain and mountainous regions, S. S. NEUSTRUEV (NÉOUSTROUEFF) (*Pochvovéděnie (Pédologie), 17 (1915), Nos. 1, pp. 62-73; 2, pp. 51-59*).—This is a classification of soils with reference to topography and climate. It is pointed out that the soils are influenced by the climatic zone regardless of the relief in the zone.

Separation of oxids of iron and aluminum in sandy and pebbly soils of Finland, B. AARNIO (*Pochvovéděnie (Pédologie), 17 (1915), No. 3, pp. 1-23*).—This article deals with the formation of ortsand and ortstein and related combinations and gives tables of analyses of samples of these materials from Hannover, Holstein, Pomerania, and Finland.

Ferrification in soils, P. E. BROWN and G. E. CORSON (*Soil Sci., 2 (1916), No. 6, pp. 549-573, figs. 8*).—The literature of the subject is reviewed and tests

of methods of determining iron in soil and of the ferrifying power of soils are reported. The conclusions reached are as follows:

"Ferrification and deferrification are processes common to the soils used in this study. The degree of ferrification and deferrification may depend upon many factors, such as organic matter content of the soil, cultivation, moisture, temperature, and food supply. An incubation period of one week in solutions is not sufficient time to allow the organisms to develop and bring about ferrification. There is no relation between the organic matter content of the soil and its ferrifying power when solutions are used. The cultivated soil has the greatest ferrifying power. Sterile water to which is added 0.1 gm. of ferrous carbonate is the best medium for the growth of the bacteria causing ferrification in solutions.

"Sand, with the addition of 0.1 gm. of ferrous carbonate and maintained at an optimum moisture content with distilled water, represents more nearly the conditions of moisture, temperature, and aeration in the field than do the solutions. When sand is used as a medium for the growth of the bacteria, it appears that the ferrifying power of the soil is related to its organic matter content. Where there was a high percentage of organic matter, there was a corresponding increase in ferrification. When the soil was low in organic matter, deferrification took place.

"The use of pure cultures of bacteria indicates that the common soil organisms, as well as the iron bacteria, are able to bring about ferrification. Molds as well as bacteria are capable of oxidizing ferrous iron."

A list of 16 references to the literature of the subject is given.

Contributions to our knowledge of soil fertility.—XII–XIV, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 39 (1914), pt. 4, Nos. 156, pp. 839–850; 160, pp. 631–645, 724–733).—Three studies are reported.

In the first paper the action of toluene on protozoa in different soils is taken up. With a poor alluvial soil in moist condition it was found that the ciliates survived a treatment of 1.5 per cent toluene and were killed by 2 per cent, while amœbæ survived a 2 per cent treatment. In the air-dried soil the ciliates and amœbæ survived a 20 per cent treatment. With a sandy soil in moist condition ciliates survived 1 per cent and were killed by 2 per cent toluene, and amœbæ survived 2 per cent but were killed by 5 per cent. In the air-dried soil both ciliates and amœbæ again survived 20 per cent toluene.

The theory that certain bacteria may have an influence upon the development of the fauna in treated soils was not substantiated. It was further found that "if the conditions are such that a reduction of sulphate is possible, as, for example, in soils containing much organic matter, there is the possibility that the action of a volatile disinfectant, by destroying some of the groups of the sulphur-oxidizing bacteria, may indirectly affect the growth of the protozoa, and especially of the ciliates."

In further tests of air-dry soils, "treatment with varying quantities of toluene showed that all percentages up to 20 failed to destroy the protozoa, taking *Colpoda cucullus* as being typical of the ciliates, *Cercomonas* or *Treponomas* as representing the flagellates, and the usual *Amœba limax* or *lobosa* for the amœbæ. . . . The experiments show that there is considerable irregularity either in the effect of the disinfectant or in the capability of growth after treatment. It appears that toluene has little disinfecting action when the moisture content is lower than from one-tenth to one-twentieth of the water-holding capacity of the soil and that when soils are quite moist amœbæ and flagellates may not be affected to any great extent. . . . It appears to make no difference whether the water is originally present in the soil or is added at the time of toluening. . . . Omitting the flagellates, which appear irregular, the

action of heat upon the protozoa is very similar to the action of the volatile disinfectants. . . .

"Regarding the action of toluene upon the bacteria, there is indicated, in the formation of the sulphid, the probability that certain oxidizing organisms in the wet soils are, by the treatment, either destroyed or overwhelmed in numbers by the surviving reducing bacteria. In dry soil this does not occur. Conditions which cause the apparent destruction of the sulphur-oxidizing bacteria also cause the destruction of the ciliates."

In the second paper, experiments with garden soil are reported, from the results of which it is concluded that "the formation of toxins in the soil free from vegetation occurs most rapidly when the temperature is near 28° C. and the moisture content is one-fourth of the water-holding capacity. The soil extract is, as a rule, either nutritive or toxic according to the volume of water, relative to the soil, used in preparing the extract. It is most nutritive when the ratio of soil to water is 1:0.5, and most toxic when it is 1:1.

"A previous drying or chloroforming of the soil generally causes the extract to be much more nutritive than when the raw soil is used. The addition of small quantities of dextrose to soil brings about a more rapid production of toxin, while aeration of the treated soil accelerates the formation and decay of the toxin."

Experiments are reported in the third paper in which it was found that chloroform acts as a stimulant in soil extracts. It is considered justifiable to conclude that chloroform will act in the same manner in soil moisture. "Its persistence in the soil after treatment, combined with its action in soil extracts, argues in favor of the stimulation theory that the great increase in the bacterial numbers, following treatment of a soil with chloroform, is due in part to the stimulation of the bacteria by small doses of the disinfectant retained by the soil."

The organic matter of the soil.—II, A study of carbon and nitrogen in the seventeen successive extracts; with some observations on the nature of the black pigment of the soil, R. A. GORTNER (*Soil Sci.*, 2 (1916), No. 6, pp. 539–548, fig. 1).—Supplementing a previous paper of this series (E. S. R., 36, p. 512), an account is given of a further study of the hydrochloric acid and sodium hydroxid extracts of a silt loam soil. Examinations of these extracts as well as of the residual soil at different stages of the extraction confirmed the author's previous conclusion that 4 per cent sodium hydroxid solution does not dissolve the black soil pigment. This pigment was found to be soluble in very dilute sodium hydroxid solutions, but precipitates from solution on the addition of sodium hydroxid in sufficient amount to make a 4 per cent solution.

"The soil pigment is also precipitated from solution by salts of the heavy metals and by acidification, is not dialyzable, and forms a stable water-soluble compound with ammonia when an ammoniacal solution is evaporated to dryness. Two attempts were made to prepare the soil pigment in pure form, but the resulting products contained such a high content of ash (37.47 per cent and 51.17 per cent, respectively) as probably to render the ultimate analysis unreliable. The analysis of the product with the least ash content gave carbon 61.3 per cent; hydrogen 4.3 per cent; nitrogen 2.8 per cent; oxygen 31.6 per cent; all calculated to an ash-free basis. The first six extractions with NaOH removed relatively more nitrogen than carbon from the soil, but the remaining three NaOH extractions as well as the six pigment solutions contained relatively more carbon than nitrogen. The final soil residue had a carbon-nitrogen ratio very much higher than that of the original soil."

References to the more important literature on the subject are given.

The influence of various cations upon the rate of absorption of ammonium ion by soil, K. MIYAKE (*Soil Sci.*, 2 (1916), No. 6, pp. 583-588).—From a study of the mechanism of absorption of the ammonium ion by a loam soil, the author draws the following conclusions:

“The relation between the time which a solution of ammonium chloride has remained in contact with soil and the amount of ammonia absorbed by the soil is expressed by the equation  $x=Kt^m$  even in the presence of another chloride in solution. The presence of other chlorides decreases the rate of absorption of ammonia from ammonium chloride solution by the soil. The retardation increases with the concentration of salt employed. Salts differ in their power of causing retardation of the rate of absorption of ammonia. The retarding effect of the salts employed increases in the following order:  $\text{Na} < \text{Mg} < \text{Ca} < \text{Al} < \text{K}$ . The value of  $Km$ , which we term the coefficient of absorption in this case, decreases with increasing concentrations of the salts, the acceleration of the decrease being positive in the cases of  $\text{NaCl}$ ,  $\text{MgCl}_2$ , and  $\text{CaCl}_2$ , and negative in the cases of  $\text{AlCl}_3$  and  $\text{KCl}$ .”

A list of references to literature bearing on the subject is given.

Effect of irrigation water and manure on the nitrates and total soluble salts of the soil, F. S. HARRIS and N. I. BUTT (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 9, pp. 333-359, figs. 18).—Experiments were conducted at the Utah Experiment Station to determine the effect of varying quantities of soil moisture and manure on the total soluble salts and nitrates that can be extracted by water from soil kept in the laboratory, soil kept for long periods in large tanks, and normal field soil. Comparisons were also made of cropped with uncropped soils in tanks and in the field.

It was found that “with a sod soil held in the laboratory for 2.5 years, the total salts and nitrates accumulated most rapidly with a moisture content between 23 and 28 per cent. Cropped and uncropped soil kept in large tanks under controlled moisture conditions showed a decrease in nitrates and total soluble salts as the percentage of moisture increased, the nitrates being particularly low in water-logged soil. Under field conditions more nitrates were found in both cropped and fallow soils during the summer than just after the corn crop was harvested.

“The nitrates of the fallow field soils averaged higher with a manuring of either 5 or 15 tons to the acre than with no manure, but on the cropped soil, although the 15-ton application of manure resulted in more nitrates than no manure, the 5-ton did not. The fallow soil showed the effect of the manure on the nitrates more in the top 2 or 3 ft. than at lower depths.

“The highest soluble-salt content of fallow soil was on plats manured at the rate of 5 tons to the acre; the lowest was on plats receiving 15 tons. The corresponding high and low points in cropped soil were on plats receiving no manure and 5 tons to the acre, respectively.

“Unirrigated land contained more nitrates than irrigated on both cropped and uncropped plats. Increasing the irrigation water applied to the soil decreased its nitrate content. The total soluble salts in cropped plats decreased as the water applied increased, and in fallow soil an application of 40 in. of water resulted in less salts than where no irrigation water was added. The treatment affected the salts more in the surface foot than at greater depths with small irrigations, but when 20 in. of water or more were applied some of the salts seemed to have moved below 10 ft. in depth. Large irrigations decreased the soluble salts in cropped more rapidly than it did in fallow soils.

“Manuring or irrigating the soil affected the nitrates relatively more than the total salts. In unmanured soil the nitrate content was about twice as great with a fallow as with a crop and in manured it was about three times as great.

"The ratio of total soluble salts to the quantity of sodium nitrate found in a cropped soil rose from 24.5:1 without irrigation to 37.5:1 when 40 in. of water were used. The ratio in fallow soil increased from 8.9:1 with no irrigation water to 16.2:1 with 40 in.

"The field results do not indicate a close relationship between the crop yield and the total soluble-salt or the nitrate content of the soil if the differences between cropped and fallow soils indicate the amounts of these substances which the crop used."

It is considered evident from these results "that the soluble salts and especially the nitrates are found in lower concentrations in soils receiving large quantities of irrigation water than in those receiving less water."

Seventeen references to literature bearing on the subject are appended.

The influence of bacteria in manure on the decomposition of green manure (legume and nonlegume), J. G. LIPMAN and A. W. BLAIR (*New Jersey Stat. Rpt. 1915, pp. 223-229, pl. 1*).—This is an account of a continuation of experiments previously described (E. S. R., 34, p. 129), in which cow manure was used.

It was found that manure has "an influence aside from any effect which may be attributed to fertilizing constituents which it contains. While there is not positive proof that this beneficial effect is due to the more thorough decomposition of organic matter by bacteria introduction in the manure, such a conclusion seems fairly warranted. Without exception the yields of grain and nitrogen were greater on the legume section than on the nonlegume section."

Farm manures, R. B. DUSTMAN (*W. Va. Col. Agr. Ext. Dept. Circ. 97 (1916), pp. 16, figs. 4*).—This is a circular of popular information on the proper conservation and use of farm manures, based on a summary of experimental evidence obtained from a number of the State experiment stations.

Report on the fertilizer industry, August 19, 1916 (*U. S. Fed. Trade Com., Rpt. Fert. Indus., 1916, pp. XX+269, pls. 10*).—This report deals with the production and sale of various forms of nitrogenous fertilizers, phosphates, potash salts, and mixed fertilizers, and also with wholesale prices and farmers' prices of fertilizers. The figures on which the report is based do not, as a rule, cover a later period than the year 1914. It is estimated that the total value of fertilizers consumed in that year was in excess of \$150,000,000. Of the approximately 7,500,000 tons of fertilizer consumed 6,750,000 tons, or 80 per cent, were mixed goods.

"Most of the fertilizers used in this country are purchased in mixed form and not in the form of materials. In the mixed fertilizer industry there are about 800 concerns operating some 1,200 plants, but the seven largest companies, with their numerous subsidiary and affiliated concerns, control more than 58 per cent of the total output. The two largest sell annually over a million tons each, and in the aggregate about 34 per cent of the total output." The combined statement of earnings and expenses of four large fertilizer companies for the period 1910 to 1914 "shows that while net sales increased 42 per cent, total expense increased 54 per cent and profits decreased 18 per cent. The increase in manufacturing cost and selling expense was about equal."

The report states "that the price movements of materials, except potash salts, are controlled fundamentally by conditions of supply and demand. The prices of nitrate of soda and sulphate of ammonia are considerably influenced by conditions in the European beet-sugar industry, while the prices of the organic ammoniates are affected largely by domestic crop conditions. Cottonseed meal prices usually follow the trend of corn prices and influence the course of prices of the other organic ammoniates—tankage, dried blood, and fish scrap. As a result of these factors the trend of prices of the inorganic and the organic nitrogenous materials show little relation to each other. The prices of nitrate of

soda and sulphate of ammonia have been high at times when the prices of tankage and cottonseed meal were low, and vice versa." The possibility of substituting one nitrogenous fertilizer for another has, however, tended to steady prices and to prevent control of prices by combinations.

"The prices of phosphate rock and acid phosphate—the principal phosphatic materials—are also determined largely by domestic conditions, among which may be mentioned the prices of cotton on the demand side and the tendency to over-production of Florida phosphate rock and of sulphuric acid on the supply side, these two materials being the constituents of acid phosphate." "The wholesale prices of German potash salts have been arbitrarily controlled by a syndicate of producers, of which the Prussian Government is a member, competition in prices having been eliminated since 1910 by an imperial law." Supply and demand, in the main, control the prices of mixed fertilizers.

"Farmers' prices of fertilizer materials for cash purchases in carload quantities have compared favorably with wholesale prices, but farmers' credit prices have often been excessively high. . . . The prices paid by farmers for mixed fertilizers have been high in comparison with the cash value of the constituent elements, partly because of credit conditions and the expensive distributing methods of the large fertilizer companies. . . . An important feature of the fertilizer industry in recent years has been the rapid increase of local dry-mixing concerns, especially in the cotton-growing States, and the activities of concerns engaged in selling fertilizer materials and in spreading a propaganda for home mixing. The competition of these concerns has had an important effect on the mixed-fertilizer business."

Some observations on the present status of the subject of the availability of nitrogen in fertilizers, C. B. LIPMAN (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 2, pp. 189-191; *Rpt. Chem. Control Com., Nat. Fert. Assoc., Meeting Fert. Div. Amer. Chem. Soc.*, 1916, pp. 3-6).—This is a review of work conducted mainly at the California Experiment Station, the purpose being to bring out "that the nitrifiability of fertilizers as determined by some laboratory method is a reliable guide to the determination of their availability, that soils of different climatic regions differ markedly in that respect, and that the standards on the availability of nitrogen in different fertilizers as previously established under humid soil conditions will probably have to be revised for arid soils at least."

The availability of nitrogenous materials, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stat. Rpt. 1915*, pp. 195-203, pls. 2).—Pot experiments with barley on white sand confirmed the results of previous experiments (E. S. R., 34, p. 129) in that they showed the amount of nitrogen recovered from sodium nitrate, ammonium sulphate, and organic materials to be in the order in which the materials are named. In further experiments on sandy loam soil calcium cyanamid stood second to sodium nitrate in percentage of nitrogen recovered, but in yield of dry matter dried blood was second and ammonium sulphate third. Ammonium nitrate gave only a low yield.

Pot experiments with barley on sandy loam soil to determine the availability of ammonium sulphate when used in varying amounts with and without lime showed that the yield increased with the increase of the ammonium sulphate applied up to a certain limit. Limed and unlimed sections were very much alike, although more nitrogen was recovered from the limed than from the unlimed sections.

Experiments with white sand to compare green manures with commercial nitrogenous materials, showed that the largest yield of barley was obtained with sodium nitrate, followed in order by ammonium sulphate, dried blood, and tankage. The yields with alfalfa, vetch, and Canada field peas did not

differ greatly and stood between the tankage and dried blood. Of the nonlegumes, timothy stood ahead, but all were low, the yields with green wheat and rye being only a little more than the check. The percentages of nitrogen in the dry matter were fairly constant, the lowest being 0.85 per cent, and the highest 1.117 per cent. The highest recovery of nitrogen was 66 per cent with nitrate of soda. The ammonium sulphate, dried blood, and tankage followed in the order named. The highest recovery with the green legumes was 39 per cent, with Canada field peas, and the lowest 35.1 per cent, with alfalfa. The highest recovery with the nonlegumes was 19.3 per cent, with timothy, while both the others fell below 5 per cent.

"The results emphasize the desirability of the legumes as a green manure crop rather than the nonlegumes, for not only do the legumes furnish more nitrogen but that which they do furnish is far more available."

Further experiments on sandy loam soil showed that the percentages of nitrogen recovered were lower in all cases than in the first experiments. Nitrate of soda stood first with ammonium sulphate second. The recovery with Canada field peas was almost equal to the recovery from ammonium sulphate, while the recoveries from the blood, tankage, alfalfa, and vetch were somewhat lower but ran very close together. There was no recovery from rye and less than 1 per cent from wheat.

**Nitrogen utilization in field and cylinder experiments:** The influence of the mechanical composition of the soil on the availability of nitrate of soda and dried blood, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt. 1915, pp. 213-223, pls. 4*).—This is an account of a continuation during 1915 of experiments begun in 1911 (*E. S. R., 34, p. 130*).

"For the first crop, the cylinders to which nitrate of soda and dried blood were applied invariably gave higher yields of dry matter than the check cylinders. Likewise nitrate of soda invariably gave a higher yield of dry matter and a higher recovery of nitrogen than dried blood. The percentage of nitrogen in the dry matter ran quite uniformly for the different treatments and throughout the different series. The average recovery of nitrogen from nitrate of soda for all series, first crops, was 54.89 per cent, and the average for dried blood 43.28 per cent. The highest recovery from nitrate was 64.09 per cent from cylinders containing 20 per cent of sand, and the highest from dried blood was 49.93 per cent from cylinders containing pure shale soil. Taking 100 as representing the availability of nitrate nitrogen, on the same basis the availability of dried blood nitrogen was 79.11.

"With the second or residual crop the average yield of dry matter with dried blood was somewhat greater than the average with nitrate of soda or the average on the check cylinders. The average on the check cylinders was almost as great as that from the nitrate cylinders. . . . In three out of the ten series there was no recovery of nitrogen from the nitrate cylinders, and in most cases the recoveries from the other seven were low. There was some recovery from dried blood for all series, the average being 6.32 per cent. In spite of the fact that the dried blood shows a higher recovery in the residual crop than nitrate of soda, when the combined recoveries are considered it is found that the nitrate stands first in all series except [one]. The average combined recovery for nitrate was 57.02 per cent and for dried blood 49.6 per cent. Again taking 100 as representing the availability of nitrate nitrogen for the combined crops, the availability of dried blood is represented by 86.36."

**Lime as a factor in the utilization of nitrogen,** J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt. 1915, pp. 204-213, pls. 2*).—Experiments on the influence of liming on the utilization of nitrogen in acid soils showed that "with an abundant supply of organic matter and carbonate of lime a crop is obtained

which is richer in protein and therefore higher in feeding value than one grown with a deficiency of these materials, even though the former be no more in quantity than the latter." The importance of carbonate of lime is further shown "in making available the nitrogen of the soil organic matter, and also in making conditions favorable for the accumulation of atmospheric nitrogen by means of leguminous crops."

Banana stalks as a source of potash, H. E. BILLINGS and A. W. CHRISTIE (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 2, pp. 153, 154).—Analyses made at the California Experiment Station of dried banana stalks obtained from fruit markets showed that they contain as much potash as kainit and compare favorably with dried kelp as filler for commercial fertilizer. Charring and leaching of banana stalks yielded 27 lbs. of 90 per cent potassium carbonate per ton. The possibility of collection and treatment on a small scale is suggested.

Production of potash in 1916 (*U. S. Geol. Survey, Press Bul. 310 (1917), p. 1*).—It is estimated from nearly complete statistics collected by the U. S. Geological Survey that "the total production of potash salts and potash products in the United States in 1916 was close to 10,000 tons of potash ( $K_2O$ ), with a net value at point of shipment of at least \$3,500,000, figured at the prevailing selling prices." This is ten times the value of the production reported for 1915 and it is thought that the total for 1917 will be still greater. The production in short tons of available potash was as follows: Natural salts or brine 3,850, alunite and silicate rocks, including furnace dust recoveries, 1,900, kelp 1,110, ashes 220, and miscellaneous industrial wastes 1,750.

The largest output came from the Nebraska alkali lakes, but natural saline deposits elsewhere are beginning to make important contributions. It is stated that an organic source of high-grade potash similar to kelp "has been quietly developed, which has proved more productive."

Vegetation experiments: Comparison of basic slag with other phosphates, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stat. Rpt. 1915, pp. 229-234*).—This is an account of a continuation of experiments reported in 1913 (*E. S. R.*, 32, p. 518) in which basic slag was compared with other phosphates.

The experiments "indicate a somewhat higher availability for the phosphoric acid of basic slags than has generally been assigned to such materials. If they are thus available for a single crop grown in quartz sand, there certainly seems good reason for believing that they would be even more available under normal field conditions."

The relative availability of acid phosphate and raw rock phosphate in Indiana field tests, S. D. CONNER (*Jour. Indus. and Engin. Chem.*, 9 (1917), various crops made at the Purdue Experiment Station, in which acid phosphate and raw rock phosphate were compared, are reported. It was found that acid phosphate returned a crop increase over six times as profitable per acre and over seven times as profitable per dollar invested as that returned by raw rock phosphate.

"By calculating the phosphoric acid in all the crops grown, it is found that 224 lbs. of  $P_2O_5$  have been recovered in the total increase caused by acid phosphate and 147 lbs. of  $P_2O_5$  have been recovered in the total increase caused by raw rock phosphate. These amounts of  $P_2O_5$  are approximately one-twelfth of the phosphoric acid applied in the acid phosphate and one eighty-fifth of the phosphoric acid applied in the raw rock phosphate."

Raw phosphate rock as a fertilizer, C. E. THORNE (*Ohio Sta. Bul. 305, pp. 227-277, figs. 8*).—This bulletin gives a review of work bearing on the subject reported from eight state experiment stations and from German sources, and gives a more extended report of experiments conducted at the Ohio Station

since 1897, the results of which, up to 1913, have been previously reported (E. S. R., 31, p. 217).

It is concluded "that raw phosphate rock may be used with profit on land that is materially deficient in available phosphorus, but as a rule acid phosphate has proved to be not only a more effective but also a more economical carrier of phosphorus to crops under conditions which render the freight charges a relatively large part of the cost of the fertilizer. Where a different outcome has resulted it is usually found that one or both of the phosphate carriers have been used in such large quantity as to furnish more available phosphorus than the crops were able to utilize, thus making a comparative measurement of the effect of the two carriers impossible."

Sulphur oxidation in soils and its effect on the availability of mineral phosphates, J. G. LIPMAN, H. C. McLEAN, and H. C. LINT (*Soil Sci.*, 2 (1916), No. 6, pp. 499-538, figs. 5).—The literature of investigations bearing on this subject is reviewed, and experiments in which sea sand, loam, and greenhouse soil were composted with manure, sulphur, and floats and analyzed periodically for acidity and available phosphoric acid are reported.

The results of the experiments show that in all cases considerable acidity was produced as a result of the oxidation of the sulphur, and the availability of the phosphoric acid of the floats was thus markedly increased. The process was most rapid in the case of the greenhouse soil, which was rich in nitrogen and mineral plant food as well as organic matter. The sulfonation increased with the period of incubation and with conditions favoring the activity of the sulfifying organisms. The data obtained indicate "that in composting under farm conditions, one part of sulphur and two parts of floats may constitute a satisfactory combination for the production of available phosphoric acid."

A bibliography of 56 references to literature bearing on the subject is given. The action of calcium carbonate on acid phosphate, E. W. MAGRUDER (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 2, pp. 155, 156).—This article has been previously noted (E. S. R., 36, p. 325).

Value of the calcium phosphates in the vicinity of Monterey [Mexico], T. FLORES (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 34 (1916), No. 10, pp. 351-362, pls. 6).—This is a brief discussion of these phosphates.

Phosphates and phosphatic marls, L. HEIMBURGER (*Fla. Quart. Bul. Dept. Agr.*, 27 (1917), No. 1, pp. 175-177).—Analyses of 12 samples of Florida phosphates and phosphatic marls are reported.

Limestone marls and shells, L. HEIMBURGER (*Fla. Quart. Bul. Dept. Agr.*, 27 (1917), No. 1, pp. 177-185).—Analyses of 61 samples of Florida limestone marls and shells are reported.

Preliminary report on the marls and limestone of Mississippi, W. N. LOGAN (*Miss. Geol. Survey Bul.* 13 (1916), pp. 82, figs. 11).—This report discusses the limestones and marls of Mississippi by counties and gives analyses of samples from each county.

Agricultural lime analyses, H. J. PATTERSON and H. B. McDONNELL (*Md. Agr. Col. Quart.*, No. 74 (1916), pp. 15).—Actual and guaranteed analyses of 129 samples of limes and limestone and mechanical analyses of 15 samples of ground limestone and oyster shells collected for inspection in Maryland from July, 1915, to October, 1916, inclusive, are reported together with general information on the kinds and use of agricultural lime.

Cost of crushing limestone on the farm, V. HERRON (*Ohio Sta. Bul.* 303 (1916), p. 128).—The total cost of crushing limestone with a portable limestone crusher at the Clermont County farm was found to be \$2.40 per ton as against a purchase price for ground limestone, including freight and hauling, of \$2.89 per ton.

Cost of ground limestone, C. W. MONTGOMERY (*Ohio Sta. Bul. 303 (1916), pp. 152, 153, fig. 1*).—At the Hamilton County experiment farm the total cost of crushing limestone was found to be \$1.90 per ton as against a purchase price for ground limestone of \$3.24, including freight and hauling.

Special fertilizer analyses, 1916, R. E. ROSE and F. T. WILSON (*Fla. Quart. Bul. Dept. Agr., 27 (1917), No. 1, pp. 63-81*).—Analyses of 224 special samples of fertilizers and fertilizing materials offered for sale in Florida during 1916 are reported.

Official fertilizer analyses, 1916, R. E. ROSE and F. T. WILSON (*Fla. Quart. Bul. Dept. Agr., 27 (1917), No. 1, pp. 82-103*).—Actual and guaranteed analyses of 180 official samples of fertilizers and fertilizing materials collected for inspection in Florida during 1916 are reported.

Inspection of commercial fertilizers, 1916, H. D. HASKINS, L. S. WALKER, C. P. JONES, and W. A. ALLEN (*Massachusetts Sta. Control Ser. Bul. 6 (1916), pp. 93*).—This bulletin gives a list of fertilizer brands registered in Massachusetts in 1916, and reports the results of actual and guaranteed analyses of 800 samples of fertilizers and fertilizing materials collected for inspection in the State during 1916. A summary is given showing average composition, cash price, and cost per pound, of each element of plant food, and special attention is called to commercial shortages and to the general character of the plant food contained in brands of mixed complete fertilizers and ammoniated superphosphates. Twenty-five per cent of the mixed complete fertilizers analyzed fell below the guaranty, over half of these being deficient in potash. On the average 51.7 per cent of the total nitrogen in the complete fertilizers was present as nitrates and ammoniates, while 48.3 per cent was present as organic nitrogen. Tests by means of the alkaline permanganate method gave additional proof of the low availability of some of the organic nitrogen.

A summary is also given of several hundred tests of the lime requirements of Massachusetts soils.

### AGRICULTURAL BOTANY.

The physiology of cell division, G. HABERLANDT (*Sitzber. K. Preuss. Akad. Wiss., 1913, XVI, pp. 318-345, figs. 7; 1916, XLVI, pp. 1096-1111, figs 3*).—The work reported in these two articles was carried out first with sections from potato tubers, then with material from stems of other plants, and finally with leaf sections. It is said to have given increasing evidence that a stimulating substance is separated from the phloem bundles, which, in connection with wound stimulus, causes or promotes cell division and growth in the tissues in the immediate neighborhood of the vascular bundles.

On the liquid pressure theory of the circulation of sap in plants, SARAH M. BAKER (*Abs. in Rpt. Brit. Assoc. Adv. Sci., 85 (1915), pp. 722, 723*).—The author, discussing two main current theories regarding the ascent of sap, proposes one based primarily upon the ecological evidence that high trees grow only where water vapor can have access to their roots.

It is stated that when either drought, low temperature, or an excess of liquid water decreases the vapor supply beyond a certain limit, trees disappear and the new plants which appear show marked xeromorphy. Experimental evidence is said to support the theory which assumes that the root hair zone is specialized for salt absorption and permeable to liquid water, likewise that the growing region of the root tip is impermeable to liquids but permeable to water vapor (hence called aeropermeable), this region also being concerned in the pumping efficiency of the root tip. Such an aeropermeable membrane, permitting liquids to pass in one direction but not in another, would render avail-

able the liquid pressure generated by a chemical reaction (respiration) which produces water at the expense of a gas, or by a physical change of state, producing water by the condensation of vapor. This latter mechanism, according to the theory here proposed, is responsible for root pressure. The condensation involves a direct conversion of energy, 90 per cent of the latent heat of vapor being theoretically convertible into liquid pressure. The ultimate source of energy is the combined action of capillary imblition and solar heat on soil particles of different sizes, which produces a slight supersaturation in the soil interstices.

The second function of the root, the absorption of nutrient salts, is supposedly effected by alternate extrusion and absorption through the root hairs of an acidic solvent. It is further suggested that in plant circulation, the whole upward current is in the xylem and the downward movement in the phloëm, the medullary rays maintaining the continuity at all levels.

The cryoscopic constants of expressed vegetable saps as related to local environmental conditions in the Arizona deserts, J. A. HARRIS, J. V. LAWRENCE, and R. A. GORTNER (*Physiol. Researches*, 2 (1916), No. 1, pp. 49).—The results of the studies here outlined are considered to show that concentration of the cell sap, in the plants characteristic of different habitats, shows a certain differentiation. The average values obtained are lowest for the arroyo or sandy wash, then successively higher for the canyons and foothills, the sandy slopes, the bajadas or mesalike slopes, and finally the salt spots. For the region as a whole, within working distance of Tucson, Ariz., the cryoscopic determinations show concentrations for trees and shrubs of 28.1, dwarf and half-shrubs 21.45, perennial herbs 16.35, and winter annuals 14.73 atmospheres.

Depression of the freezing point in triturated plant tissues and the magnitude of this depression as related to soil moisture, R. P. HIBBARD and O. E. HARRINGTON (*Physiol. Researches*, 1 (1916), No. 10, pp. 441-454).—The work here outlined, employing material from potato tubers, cabbage head leaves, apples, lemons, oranges, grapefruits, onion bulbs, and maize roots and tops, is considered to show that the lowering of the freezing point in ground plant tissues is as valuable a criterion for the comparison of osmotic concentrations in the tissues as is the corresponding index for the expressed sap. The material, after being frozen, then triturated, and finally tested in a Beckmann freezing-point apparatus, gave concordant results from different samples of the same pulp and from pulps as compared with juices expressed from samples of the same pulp, provided the pressing had been thorough. Thus the determination of the freezing-point depression and of the osmotic concentration of tissues is rendered more simple, though the method is admittedly inapplicable to very small quantities of materials.

By this method, material from maize roots showed a much lower osmotic concentration than did material from the aerial portions.

Studies of protoplasmic permeability by measurement of rate of shrinkage of turgid tissues.—I, The influence of temperature on the permeability of protoplasm to water, E. M. DELF (*Ann. Bot.* [London], 30 (1916), No. 118, pp. 283-310, figs. 17; abs. in *Rpt. Brit. Assoc. Adv. Sci.*, 85 (1915), pp. 723-725, fig. 1).—Developing a method of measuring indirectly changes in the permeability of protoplasm to water by ascertaining the changes in the rate of shrinkage of tissue bathed in solutions tending to plasmolyze the cells, the author studied the changes in protoplasmic permeability corresponding to temperature changes between 5 and 42° C. In discussing the tissue shrinkage obtained in dilute sugar solution, he states that the permeability of protoplasm for water is increased by increase in temperature so far as studied (up to about 42°),

the several values being tabulated. An approximate measure of the increase is furnished by sets of temperature coefficients shown for each rise of 10° between 5 and 40° by the onion leaf and dandelion scape.

Further studies on foliar transpiring power in plants, A. L. BAKKE and B. E. LIVINGSTON (*Physiol. Researches* 2 (1916), No. 2, pp. 51-71, figs. 3).—These studies carry forward the work previously reported (E. S. R., 34, p. 334), employing herein *Xanthium canadense* and *Helianthus annuus*. The tests were made on leaves of various ages and at different hours.

The results are said to agree throughout in showing a daily cycle of change in the average foliar transpiring power of the plant, as a whole, from low night values to high day values and vice versa, as already ascertained in other plants. The maximum value of the average index of foliar transpiring power occurred about the tenth hour of the day in July and August, the two plants behaving much alike in this respect. The minima occurred about the eighteenth or else about the twenty-second or twenty-third hour of the day, and are also much alike for the two plants. Apparently the diurnal is three to five times the nocturnal transpiring rate. The increase occurring within one hour from just before sunrise to just after amounts to 240 per cent in *Xanthium* and 90 per cent in *Helianthus*. Older branches attain to lower maximum values and have more restricted daily ranges.

A single index to represent both moisture and temperature conditions as related to plants, B. E. LIVINGSTON (*Physiol. Researches*, 1 (1916), No. 9, pp. 421-440, fig. 1).—This is a more detailed account than that previously noted (E. S. R., 35, p. 732).

The respiration of partly dried plant organs, A. M. SMITH (*Abs. in Rpt. Brit. Assoc. Adv. Sci.*, 85 (1915), p. 725).—Tests were made with such plant organs as leaves of snowdrop, stem tips of *Tropæolum*, and young stems of asparagus, by depriving them, by means of a vacuum desiccator, of different proportions of the water they contained and then measuring their output of carbon dioxid.

The results show that in some cases respiration was increased after the plants had been deprived of one-third to one-half of their water content. The experiments thus far completed, while inconclusive, do not indicate reversibility in this process.

Investigation of the course of respiration with various degrees of deprivation of water content (fresh plants being used for each test) showed three phases of the course of the resulting respiration. Up to about 30 per cent of water loss, the increase of respiration was proportional to the loss of water. Respiration then remained about the same during a decrease of water content ranging from 25 or 30 per cent up to 50 or 60 per cent. Above this limit to that of complete dryness, respiration decreased proportionally to the amount of water lost.

The meaning of the increased protoplasmic respiration in partly dried material is deemed not clear. It has been suggested that the increased respiration shown in these experiments may be due to the increased activity of one or more enzymes.

Physiological studies on the maturation of seeds, S. L. IVANOV (*Soobshch. Büro Chastn. Rast. [Petrograd]*, 3 (1916), No. 2, pp. 49).—The author, reporting upon a series of studies with pure lines of peas, flax, wheat, and oats, claims that the capacity of being changed into insoluble forms is the chief factor in the transmission of mineral and organic substances from stem to seed. In case of annuals the maturing of seeds exhausts the plant and thus leads eventually to its death. The process of maturation of the seeds has a

decided influence on the development of the fruit. In legumes the growth of each seed influences the development of the corresponding portion of the fruit. The transfer of food from stem to seeds begins after the processes which determine seed shape have been completed.

Under the influence of a humid atmosphere the yield of cereals was reduced while that of peas was increased, the ash content of peas and wheat was increased while that of oats was lowered, albuminoid substances were increased in all seeds, and the oil content of flax was slightly diminished. Shading lowered the yield of oats and peas but that of wheat was somewhat increased. The ash content was generally increased, as was also the albuminoids in peas and wheat. Slight shading resulted in an increase in the starch content of seeds, while the oil content of flax was lowered. The quality of the oil was not influenced by slight shading, but with heavy shade the iodine number was below normal.

A resting period for a variety of durum wheat was found to be unnecessary as the seed would readily germinate before complete maturity.

The formation of auxinones from nitrogenous organic substances, W. B. BOTTOMLEY (*Abs. in Rpt. Brit. Assoc. Adv. Sci.*, 85 (1915), pp. 728, 729).—A method for investigating the presence of auxinones has been developed in consequence of the observation that on crude nitrifying culture solutions containing these substances, a bacterial scum is formed. It has been found that during the germination of seeds, auxinones are formed, and that they enable the embryo to utilize the food materials in the seed. Auxinones are formed during the humification of nitrogenous organic matter, and the amount of auxinones present depends upon the extent of humification. Fresh manure, rotted manure, and bacterized peat have been found to contain auxinones in the proportion of 1:5:250. Experiments carried out as described, on *Lemna minor* growing in Detmer's culture solution, are considered to show that the purer auxinone silver fraction is more effective on growth than the cruder phosphotungstic fraction.

The location of spore masses in the Uredineæ and its value as a character in classification, F. GREBELSKY (*Centbl. Bakt. [etc.]*, 2. Abt., 43 (1915), No. 25, pp. 645-662, figs. 12).—Concluding a study of several species, mainly of *Puccinia* and *Uromyces*, on various hosts named, the author states that a close and almost universal relation may be asserted between the position of the spore masses and that of the stomata as dorsal or ventral in case of the uredospores. The same is true in a considerable degree in case of the teleutospores.

The position of the spore masses can not, then, be regarded as a systematic character unless it be indirectly, in so far as choice of host is a species character, certain species living on hosts which have stomata on the one or the other leaf surface. For some other species the position of the teleutospores is characteristically independent of that of the stomata. It is, therefore, necessary to know the degree of dependence or independence in this respect in employing the position of spore masses as a species character. As regards those cases where the spore masses lie beneath the stomata, further investigation is required regarding the part played by the influence of negative hydrotropism and the advantages of access to oxygen.

Studies on the succession and ecology of epiphytic bryophytes on the bark of common trees in Denmark, C. OLSEN (*Bot. Tidsskr.*, 34 (1917), No. 7, pp. 313-342, figs. 4).—The author reports that epiphytic bryophytes are always found in woods on one side of the tree stem and not on the other. This is accounted for by the fact that most forest trees deviate from the perpendicular more or less, and it is on the upper sides of such trunks that the mosses are

found. Their occurrence on the upper side of the trees is explained by the fact that rain in a wood nearly always falls vertically, with the result that the upper side of the tree trunk, being more exposed, obtains a greater share of the rainfall than the lower. The bryophytic vegetation is said to be most abundant upon trunks with an inclination of more than  $10^\circ$ , while on perpendicular trunks such vegetation is very nearly or entirely lacking.

With trees standing in the open, a more upright habit of growth results, and the occurrence of bryophytes on trunks is as a rule infrequent, but where they are found, they may occur on all parts of the stem. This is claimed to be due to the fact that in open ground the rain may come from all quarters. On such isolated or exposed trees, lichens are of more frequent occurrence than mosses.

A note on the inheritance of eye pattern in beans and its relation to type of vine, F. M. SURFACE (*Amer. Nat.*, 50 (1916), No. 598, pp. 577-586, figs. 3).—The author has made a genetic study of the two types of beans previously mentioned (*E. S. R.*, 33, p. 635), carrying a few to the  $F_2$  generation.

In addition to the two parent types, a third appeared in both the  $F_1$  and  $F_2$  generation, showing a piebald pattern as regards color distribution. This is thought to be the expression of the heterozygous condition of the factorial differences between the parent types. A provisional hypothesis for the types thus far known is outlined on the basis of the admittedly scanty data which have been obtained. Apparently the gene for the bush type of vine is closely associated with that for one of the original patterns.

A quantitative study of the factors influencing the weight of the bean seed.—II, Correlation between number of pods per plant and seed weight, J. A. HARRIS (*Bul. Torrey Bot. Club*, 43 (1916), No. 9, pp. 485-494, figs. 4).—This study, made in pursuance of those previously noted (*E. S. R.*, 32, p. 521), showed that throughout the 27 series of cultures used, representing five varieties, the correlations for seed weight and number of pods per plant were positive, but of small magnitude and variable. In both average magnitude and variability the correlations for seed weight and number of pods per plant agreed very well with those for ovule per pod and pods per plant and with those for seeds per pod and pods per plant.

The average value of the correlation for pods and weight was lower than that for pods per plant and ovules per pod, and higher than that for pods per plant and seeds per pod, but both of these differences are low and may not be significant in comparison with their probable errors.

On selective partial sterility as an explanation of the behavior of the double-throwing stock and the petunia, EDITH R. SAUNDERS (*Amer. Nat.*, 50 (1916), No. 596, pp. 486-498).—This is a critical discussion of portions of the preliminary paper by Frost, previously noted (*E. S. R.*, 34, p. 237).

Application of the pure-line concept to bacteria, L. J. COLE and W. H. WRIGHT (*Jour. Infect. Diseases*, 19 (1916), No. 2, pp. 209-221).—From a consideration of experiences and observations in connection with the production and study of bacterial cultures, the authors have concluded that much of the variation observed in ordinary cultures is due to the selection, by investigator or environment, of pre-existent biotypes, and the suppression or extinction of others. This leads to a temporary or permanent change in the character of the type, and, in the latter case, gives rise to a change which may be erroneously taken for a true hereditary mutation. Incomplete selection may be followed by the reappearance of a suppressed type on the restoration of former conditions.

The descendants of a single cell constitute a pure line, or clone, which can not be modified by selection, though mutation is not excluded and does occur in pure lines, both spontaneously and in response to environmental stimulus. The

new races, or biotypes, vary about modes of their own, and are not permanently modifiable. Such mutations may become appreciable only by statistical methods. The biotypes constituting ordinary bacterial cultures have arisen and persisted as mutations.

**Nitrocultures and their commercial application**, F. C. HARRISON (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 9 (1915), Sect. IV, pp. 219-223).—The author reviews the applications of the methods employed in experiments by himself in connection with Barlow (E. S. R., 17, p. 950; 19, p. 528), and gives in tabular form the results obtained in later tests by himself. He states that the best growths were found among those obtained from the alsike culture on saccharose, those from vetch culture on dextrin dipotassium phosphate, and those from alfalfa, soy bean, and red clover culture on wood ash agar. Combinations were also tried, and for the last two years 1 per cent saccharose and  $\frac{1}{2}$  per cent mannite have given good results.

The composition of the media and the mode of preparation of the cultures for distribution are described in some detail.

### FIELD CROPS.

**Contributions to agronomic terminology, II-IV**, C. R. BALL and C. V. PIPER (*Jour. Amer. Soc. Agron.*, 8 (1916), Nos. 3, pp. 197-204; 4, pp. 228-237; 5, pp. 310-315).—The glossary of agronomic terms previously noted (E. S. R., 35, p. 30) is continued. Part 2 defines 14 terms relating to plants, 10 to roots, 24 to shoots and buds, 26 to stems and branches, 29 to leaves, and 7 to epidermal appendages; part 3, 31 terms relating to inflorescence, 74 to flowers, and 80 to fruits and seeds; and part 4, terms denoting pubescence, protuberances and inflations, excretions, punctations, and perforations.

**Relative precision of formulas for calculating normal plat yields**, W. W. STOCKBERGER (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 3, pp. 167-175).—This paper discusses the precision of certain formulas commonly used for calculating normal plat yields. The methods are compared in field experiments with hops, including fertilizer tests and variations in cultural methods.

The normal yields for the plats varied widely according to the methods of computation, the values in some cases differing from the actual yield by 40 per cent. The errors introduced by the use of the formulas discussed may be remedied in part by correcting for imperfect stand and by replication. Correcting to full stand does not always result in increased precision. Replication brings about a very marked reduction in variability, although with only five replications the error is still relatively large.

**The root systems of agricultural plants**, E. C. MILLER (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 3, pp. 129-154).—This is a review of the literature on the root systems of agricultural plants gathered by the author in his studies of the roots of corn and sorghum (E. S. R., 35, p. 437). The review includes (1) the extent of root systems, including methods for their isolation, (2) the relation of the weight of roots to the aerial portion of the plant, and (3) the influence of moisture, fertilizers, and oxygen on root growth and development. A number of tables are given which, for the most part, have been abstracted and rearranged, and many new calculations made in order to bring out the most important facts. Sixty-four articles are reviewed and listed in the bibliography at the end of the paper.

[**Work with field crops in 1916**] (*Wisconsin Sta. Bul.* 275 (1917), pp. 24-34, figs. 6).—A further study by E. J. Delwiche of the problem of controlling lodging of oats has given results similar to those previously noted (E. S. R., 35,

p. 528). White Jewel has again proved to be the most resistant variety found, showing a loss by lodging of 40 per cent in comparison with losses as high as 90 per cent sustained by other standard varieties.

Owing to the open and severe winter of 1915-16 serious winterkilling of alfalfa was experienced. L. F. Graber, in tests with different strains of alfalfa originating from both northern and southern grown seed of the purple varieties, as well as variegated strains (including the Baltic and Grimm), found nine plats of northern-grown seed showed 55 per cent winterkilling and 3,840 lbs. of cured hay per acre; two plats of southern-grown seed, 52 per cent winterkilling and 4,470 lbs. of hay; one plat of an imported variety (Turkestan) 31 per cent winterkilling and 5,540 lbs. of hay; and four plats of variegated strains showed 27 per cent winterkilling and 6,045 lbs. of hay.

Observations indicate that seedings of common alfalfa are much more susceptible to winterkilling the second winter than the first. The so-called "hardy alfalfas," the seed of which was derived from 25- to 35-year-old fields in Montana and Dakota, were no more resistant to winterkilling or superior in yields than the common strains from those States.

Comparative tests of 34 different strains of alfalfa on 2- and 3-year-old growths indicate that there is no correlation between hardness and the nature of the root growth. Observations show that all of the principal strains of American grown alfalfa possess both the tap root and branched types of root systems.

Brief notes are given on Sudan grass for Wisconsin. Seedings of from 20 to 25 lbs. per acre from June 1 to 10 are recommended. An average yield of 3.5 tons of hay per acre has been secured, while a yield of 12.8 tons of forage per acre was realized when sown in cultivated rows for soiling purposes.

Of the corn varieties adapted to upper Wisconsin, Wisconsin No. 25 is recommended by E. J. Delwiche for sandy and sandy loam sections not over 1,200 to 1,300 ft. in altitude, as it matures ten days earlier than Wisconsin No. 8 (a northern bred variety) and yields approximately 75 bu. per acre. For the cooler climate and heavier soils of the Superior region Wisconsin No. 25, No. 23, Northwestern Dent, and Whitecap Dent mature sufficiently early to make good silage.

The work in wheat breeding conducted at Madison by B. D. Leith and at Ashland by E. J. Delwiche has been continued, with Pedigree No. 2 again giving the highest yields and surpassing all other varieties in milling tests as to volume of loaf. A number of pure-line selections and cross selections developed at Ashland have shown exceptional merit, some yielding 25 per cent over the standard Blue Stem type. Several of these pedigreed strains yielded from 51 to 55 bu. per acre this year, while the soft winter varieties yielded about 4 bu. more than the hard varieties. Efforts are being made to improve the rust-resisting qualities of these strains by selection.

Work with the soy bean for seed production has been continued. Pedigree No. 2 of the Ito San variety has given the best results at Madison, while Early Black has proved best for upper Wisconsin. Black Eyebrow has been found well adapted for both hay and silage purposes.

Brief notes are given on the management of sweet clover.

The development of the hemp industry has been continued under A. H. Wright. The production of fiber in 1916 was estimated at 1,500 lbs. per acre with a value of \$105. The total estimated value of the crop for the State is \$125,000. Field tests are in progress to determine the suitability of various soil types for hemp production and to ascertain whether or not hemp seed could be matured profitably in the State. Efforts are being made to improve the strains used for cultivation, especially as to early maturity, using Minnesota No. 8 for selection.

Experiments with farm crops, F. APP (*New Jersey Stat. Rpt. 1915, pp. 181-183*).—Sudan grass seeded June 15 yielded 10.2 tons of green forage as compared with 8.7 tons of Japan millet used as a check. Sudan grass did not prove exceptionally palatable when fed to cows. A seeding of this grass May 15 did not begin to make vigorous growth until late in June, while the later seeding of June 15 was vigorous from the beginning. Sudan grass is not considered far superior to the millets as a forage crop for New Jersey north of New Brunswick.

In variety tests with corn, the highest-yielding variety (a Leaming strain) produced at the rate of 67 bu. per acre and the lowest-yielding variety 26.9 bu. The variety giving the highest grain yield likewise gave the highest stover yield, at the rate of 3.66 tons per acre.

[Field crops work on county experiment farms in Ohio in 1915, C. W. MONTGOMERY ET AL. (*Ohio Sta. Bul. 303 (1916), pp. 73-102, 107-126, 129-147, 149-152, 153-166, 168-172, 174-176, 185-197, 200-207, figs. 17*).—This reports work in 1915 at the experiment farms located in Miami, Paulding, Clermont, Hamilton, and Washington counties in continuation of that previously noted (E. S. R., 33, p. 828), together with work in Hancock County last reported on in 1911 (E. S. R., 28, p. 40) and in Trumbull and Mahoning counties, which is reported here for the first time. The reports for the several farms include the results of rotation tests, including corn, oats, wheat, clover, soy beans, sugar beets, potatoes, and tobacco; fertilizer and barnyard manure experiments with the crops in rotation; liming tests; variety tests with corn, oats, wheat, and soy beans; fertilizing experiments with pasture lands and alfalfa; early and late seeding tests with wheat; a depth of plowing test with corn and soy beans; and a comparison of Sudan grass with German millet on the Paulding County farm. The data obtained from the fertilizer and barnyard manure experiments and the variety tests at all the stations are summarized in tabular form, together with data showing the direct and residual effect of chemical fertilizers and barnyard manure.

In comparing Sudan grass with millet on plats in which both were drilled solid, the Sudan grass exceeded the millet by an average of 1,250 lbs. of hay per acre.

In all cases, except on the Paulding County farm, acid phosphate has produced profitable increases in crop yields. The larger quantities of acid phosphate used in the more recent experiments have not yet produced increased yields proportionate to the quantity applied, as compared with the results at Wooster and Strongsville, the increases in these tests for the first five years amounting to 4 bu. of corn in each case and less than 2 bu. of wheat at Wooster and 5½ bu. at Strongsville.

The average increase of corn in the 12 tests has been 5½ bu., obtained with an average application of 152 lbs. of acid phosphate, and the average increase of wheat 5½ bu., with an average application of 157 lbs. The addition of an average of 50 lbs. of muriate of potash has increased the average yield of corn in the 12 tests by a little more than 2½ bu. and that of wheat by 1½ bu., sufficient to cover the cost of the additional fertilizer in either case.

The addition of 63 lbs. of nitrate of soda per acre on corn and of 83 lbs. on wheat to the combination of acid phosphate and muriate of potash resulted in average increases of only 1½ bu. of corn and 2 bu. of wheat, insufficient to cover the cost of the nitrate.

In comparing the direct and residual effects of barnyard manures in a 5-year rotation at Wooster, it was found that for the 20 years 1894-1913 the direct effect of an 8-ton application to both the corn and wheat crops amounted to increased yields conservatively valued at \$23.74 per acre, while the residual

effects resulted in increased yields valued at \$22.87 per acre. Similarly with the 4-ton application the direct increase is valued at \$14.91 and the residual at \$13.49 per acre.

A further comparison of the direct and residual effects of a complete chemical fertilizer when applied to corn and wheat and to wheat alone shows that the chemical fertilizer, which cost \$7.45 for the corn crop and \$8.60 for the wheat crop (at prices prevailing before the war), produced a direct increase valued at \$22.47, nearly the same as the 16 tons of barnyard manure, but the residual increase from the chemical fertilizer amounted to only \$11.85 per acre, or about half that from the manure. When the fertilizer was applied to wheat only, the residual increase extending through the four crops following was relatively larger than when both crops were fertilized, amounting to 80 per cent of the direct increase.

**Report of the Bugyi experimental plat for the year 1914-15, E. THOMPSTONE** (*Dept. Agr. Burma, Rpt. Bugyi Expt. Plot, 1914-15, pp. 5*).—This is a progress report of investigations being conducted near Bugyi. The objects of the project are to introduce paying dry crops, to test deep and early cultivation, and to find a good rotation crop for sesame, the principal crop of the region. Of the crops tested, pèsingôn (*Cajanus indicus*), pyaung (*Sorghum vulgare*), and pebyugyi (*Phaseolus lunatus*) are said to give promise for the future. Brief notes are also given on castor, cotton, peanut, and sesame.

**Experiments with spring cereals at the Eastern Oregon Dry-Farming Substation, Moro, Oregon, D. E. STEPHENS** (*U. S. Dept. Agr. Bul. 498 (1917), pp. 37, figs. 16*).—This bulletin deals with varietal and cultural tests of spring-sown cereals, including wheat, oats, barley, emmer, and grain sorghums, conducted at Moro, Oreg., in cooperation with the Oregon Experiment Station during the 5-year period 1911-1915, inclusive.

The substation is situated at an elevation of approximately 2,000 ft. on a silty loam soil typical of the Columbia Basin in Oregon and Washington. The average annual precipitation in this region for the past 11 years has been 11.35 in., while the average seasonal precipitation (March to July, inclusive) for the 5-year period covering these experiments was 3.83 in. The average evaporation from a free-water surface was 45.07 in. during the 7-month period April to October, inclusive, for the same period. The ratios of evaporation in seasonal and annual precipitation are higher at the Moro substation than at the Nephi, Utah, or Moccasin, Mont., substations. The average frost-free period for the 5 years was 155.8 days, with the average date of the last frost (32° F.) May 2 and of the first frost October 5. The average wind velocity was 5.9 miles per hour. Considerable meteorological data are tabulated in detail and discussed.

Seventy-six varieties of spring wheat have been tested two or more years, with Pacific Bluestem used as a standard for comparison in all checks. During the 5-year period Early Baart (C. I. No. 1697) exceeded the standard variety by an average yield of 3 bu. per acre, Koola (C. I. No. 2203-2) surpassed it by 6.3 bu. for the 3-year period 1913-1915, and Karun (C. I. No. 2200-1) by 4.9 bu. for the same period. Of all the varieties tested Early Baart gave the highest average yield, 22.2 bu. per acre, for the 5-year period, while the selection from Koola gave the highest average yield of 27.7 bu. per acre for the 3-year period.

The bearded varieties of common wheat exceeded the yield of the beardless common and club wheats by 1.7 bu. per acre.

The durum wheats have not yielded so well as the common and club varieties. The average yield of 14 varieties of the latter exceeded the average yield of

Blé Noir and Kubanka, durum wheats, by 3.5 bu. for the period 1913-1915. The average yield of the highest yielding common wheat exceeded that of the highest yielding durum wheat by 7.7 bu. per acre for the same period.

The spring wheat varieties Pacific Bluestem, Little Club, Early Baart, Karun, Koola, and Talimka, which have given the best average results, are described and discussed.

Data are given on the chemical analysis of the grain and flour of several of the spring wheat varieties tested, together with milling and baking tests conducted by the Plant Chemical Laboratory of the Bureau of Chemistry. All the varieties appear to be equal to and most of them superior to Pacific Bluestem.

Date- and rate-of-seeding tests with Pacific Bluestem indicate that seedings of about 5 pk. per acre as early in the spring as possible give the best results. For late seeding, 3 pk. per acre gave the highest yields. The average increase in yield from early seeding for a 4-year period was 6.2 bu. per acre.

Of the spring oat varieties tested, the early varieties such as Kherson and Sixty Day gave the best results, although Siberian, a midseason variety, has yielded practically as high as early varieties. The Kherson, Sixty Day, Siberian, and Canadian varieties are described and discussed.

Forty-three varieties of spring barley have been tested and 5-year average yields obtained for 13 varieties. Mariout (C. I. No. 261), a 6-rowed form, gave the highest average yield of 34.3 bu. per acre for the 5-year period. The 2-rowed forms White Smyrna and Hannchen gave average yields of 33 and 32.2 bu. per acre, respectively, for the 6-year period. The leading spring barley varieties are briefly described.

Spring emmer has not proved so drought resistant as spring wheat, oats, and spring barley. The average yield of one variety (C. I. No. 1524) for the 5-year period was 21.8 bu. (32 lbs. per bu.) per acre, or less than half the weight obtained with Kherson oats or Mariout barley for the same period.

Variety tests of grain sorghums included Manchu and White kaoliang, milo maize feterita (Sudan durra), and Kafir corn. All but Manchu kaoliang have been discarded as unsatisfactory.

Two varieties of broom corn have been tested and have given fair seed yields, but the brush is of poor quality.

The 5-year average acre yield in pounds of the highest yielding varieties of the three leading cereals was as follows: Wheat, 1,362 lbs.; oats, 1,402 lbs.; and barley, 1,646 lbs. Based on the 10-year (1905-1914) average farm price of these cereals in Oregon, the acre value of wheat would be \$18.39, of oats \$19.35, and of barley \$20.35.

Seeding winter grains in furrows to prevent winterkilling, S. C. SALMON (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 3, pp. 176-188, pls. 2, figs. 2).—This paper, from the Kansas Experiment Station, discusses numerous experiments with seeding winter grains in furrows to prevent loss through winter injury. While most of the experiments were conducted in Kansas, several investigations outside of that State are cited and numerous references made to the literature on the subject. The general conclusions drawn are as follows:

In general, grain sown with a drill survives the winter better than when sown broadcast. Seeding in furrows tends to prevent winterkilling and damage from blowing in dry areas. The furrows catch and retain snow, modify the temperature, protect the plants from wind, and probably reduce injury due to heaving. Winter oats sown in furrows survived 87.5 per cent in one season as compared with 7.5 per cent when sown in the ordinary way, and winter barley survived 87 per cent while that sown with the disk drill was entirely killed. Wheat did not show a marked advantage from seeding in furrows, (1) because wheat sel-

dom winterkills, (2) because of poor drainage, and (3) because of certain limiting factors which entered into the field tests.

It is stated that grain should not be sown in furrows where the land is poorly drained, nor on hillsides subject to erosion. This method appears to be especially promising for areas where the moisture supply is deficient, and where the winters are cold and characterized by light snowfall and frequent winds.

The effect of clipping on the root development of alfalfa, R. MCKEE (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 5, pp. 329-332).—This is a brief account of some alfalfa investigations conducted at Chico, Cal., during the seasons of 1912, 1913, and 1914.

The effect of clipping alfalfa the first season was studied with special reference to root development, and it was found that clipping materially reduced the diameter of the root immediately below the crown. The effect of clipping the first season on the subsequent yield of hay, as observed so far as the length of the experiment permits, was indicated to be that clipping the first year reduces the subsequent yields of hay, especially in the first and second season, unless the clipping is essential for weed control.

Corn.—Varieties and limiting factor tests, season 1916, W. L. HUTCHINSON (*South Carolina Sta. Bul. 190 (1917)*, pp. 7).—Tests with 16 varieties of corn at Clemson College and 17 varieties at the Pee Dee substation are reported.

Lowman Yellow gave the highest yield at Clemson College, with 43.2 bu. per acre, and Marlboro the highest at Pee Dee, with 45.7 bu. Lowman Yellow was second at the Pee Dee substation, with 44.6 bu. The lowest yielding variety at both stations was Hickory King, with 29 and 26.8 bu., respectively.

Limiting factor studies with various fertilizers were continued with the same results as previously noted (*E. S. R.*, 35, p. 338). The check plats at the Pee Dee substation, growing cowpeas with corn in a two-year rotation of corn and cowpeas and cotton, gave good yields, indicating that the soil is being improved without the aid of fertilizers.

Corn, yields per acre and prices, by States, 50 years 1866-1915 (*U. S. Dept. Agr. Bul. 515 (1917)*, pp. 16).—Tabulated statistics are given for the yield of corn per acre, prices, and values for each year of the 50-year period 1866-1915 in the United States, the several divisions of States, as North Atlantic, South Atlantic, etc., and by States.

Cotton.—Varieties and limiting factor tests, 1916, W. L. HUTCHINSON (*South Carolina Sta. Bul. 189 (1917)*, pp. 8).—Continuing work previously noted (*E. S. R.*, 35, p. 136), results of tests with 26 varieties of cotton at Clemson College and of 30 at the Pee Dee substation are reported.

It is recommended that the Webber-Columbia types of long-staple cotton be carefully selected for length of fiber, without lessening their good qualities, in order that they may be clearly grouped as long-staple varieties, even when grown under adverse conditions. The Cleveland, Cook (when free from anthracnose), Sawyer, and Pulnott are reported as having outstanding merit in the short-staple group.

At Clemson College the Webber variety was first, with a total value of \$157.54 per acre, and Columbia second with \$137.04. Of the short-staple types Simmons Cleveland stood first, with a total value of \$133.78. For the varieties tested the rate of yield of lint ranged from 272 to 608 lbs. per acre, and the percentage of lint from 28 to 40.

Alabama Cook, with a total value of \$131.92 per acre, stood first at the Pee Dee substation and Pulnott second, with a total value of \$124.39. The range in the rate of yield of lint for the varieties tested at this station was from 210 to 608 lbs. per acre, and the percentage of lint from 29 to 39.

Limiting factor studies with various fertilizers are reported in tabular form.

**Report on the manuring of mangels, J. PORTER and A. S. MCWILLIAM** (*Herefordshire Ed. Committee, Farmers' Bul. 9 (1915), pp. 9*).—This is a report of fertilizer experiments with mangels which have been in progress since 1908. Five combinations of commercial fertilizers were used in the test in addition to a dressing of barnyard manure of from 12 to 14 tons per acre. All of these fertilizer applications were made at seeding time, and on four of the five fertilized plats a top-dressing of sodium nitrate was added at singling time. The fertilizers used were ammonium sulphate, nitrolime, nitrate of soda, calcium nitrate, acid phosphate, basic slag, potassium sulphate, and sodium chlorid. All the treatments were made in triplicate at each of the 11 centers where the experiments were conducted. The general conclusions drawn from the experiments to date are as follows:

All mixtures of fertilizers when used with farmyard manure have been followed by profitable returns, the average increases varying from 4 to 7 tons per acre. A top-dressing of sodium nitrate has resulted in an average increase of mangels of 3 tons per acre, and when the nitrogen was applied in the form of calcium nitrate the same average increase was obtained at approximately one-half the cost. With ammonium sulphate slightly higher results have been obtained than with its equivalent in nitrolime. Acid phosphate on gravelly soil gave better results than basic slag, while on the heavier soils the results were almost identical. The following mixture of commercial fertilizers has given the largest increase in yield and the greatest profit: 0.5 cwt. ammonium sulphate, 3 cwt. acid phosphate, 0.5 cwt. potassium sulphate, and 2 cwt. salt applied at seeding time, with 1.25 cwt. calcium nitrate applied as top-dressing shortly after singling.

**A classification of the varieties of cultivated oats, W. C. ETHERIDGE** (*New York Cornell Sta. Mem. 10 (1916), pp. 81-172, pls. 22, figs. 22*).—This reports the development of a usable system of classification of the American varieties of oats grown in the environment of New York State in an effort to clear to some extent the confusion in varietal nomenclature. A review and discussion of the work of others has shown that a classification of oat varieties, in order to be effective, must be based on the morphology of the plant. The present classification, therefore, follows (1) a study of the morphology of the plant to discover the various characters by which individual varieties may differ; (2) an analysis of varieties en masse to reach the types which for present purposes are considered elemental, that is, types that differ in one or more morphological characteristics; and (3) an arrangement of varieties in groups regardless of nomenclature, according to their likeness to the elemental types that represent the groups. The groups are fully described and named, and a key constructed for their identification. The naming of groups consisted in applying the name that occurred most frequently among the specimens of each group, although all additional different names were reserved and arranged as synonyms.

Specimens numbering 731 have been classified in the study, the bulk of which were brought together in 1909 at the Nebraska Experiment Station by E. G. Montgomery and M. S. Jussell, who laid the foundation for this work. The original collection included all varieties then grown or offered for sale in the United States. During 1913, 1914, and 1915 this collection was supplemented by accessions from the Office of Cereal Investigations of the U. S. Department of Agriculture (with which the author cooperated) and from various other sources.

The morphology of the oat plant is discussed in considerable detail, together with a description of the important taxonomic characters, and their uses in previous classifications and in the present one explained.

The principal cultivated varieties of oats, together with their basic wild species, are classified in eight groups, the elemental types being *Avena nuda*, *A. sterilis*, *A. abyssinica*, *A. strigosa*, *A. brevis*, *A. fatua*, *A. sativa*, and *A. sativa orientalis*. Fifty-five varieties are described within the three common specific groups, *A. sterilis*, *A. sativa*, and *A. sativa orientalis*. The varieties are systematically arranged with respect to such morphological differences as appear best to fulfill the requirement of constancy in inheritance and ease of observation and which should reasonably be expected to appear under other environments. The classification takes no account of differences in ability of varieties to yield.

An extensive bibliography is appended.

Studies on oat breeding.—III, On the inheritance of certain glume characters in the cross *Avena fatua* × *A. sativa*, F. M. SURFACE (*Genetics*, 1 (1916), No. 3, pp. 252-286, pls. 2).—Continuing work previously noted (E. S. R., 33, p. 38), this paper deals with the inheritance of certain characters of the flowering glumes of the cross of *A. fatua* with *A. sativa*.

*A. fatua*, known as the wild parent, possesses the following glume characters which enter into consideration in this paper: The flowering glumes are black or dark brown in color. The lower and upper grains of each spikelet bear heavy geniculate and twisted awns. Pubescence occurs on the back of both the upper and lower grains, about the base of each grain, and on the pedicel of each grain. The base of each grain is expanded into a broad sucker-like ring which permits of easy shattering.

The grain of *A. sativa*, the cultivated parent, is yellow. Awns are completely lacking except in an occasional spikelet, where the lower grain only may possess a very weak awn. All pubescence on regions noted above is lacking. The base of the grain is narrow and contracted and the grain does not shatter.

The  $F_1$  plants are as a rule intermediates. The grain is brown in color, and medium heavy awns are present on the lower grain of some spikelets, although no awns are ever found on the upper grain. The lower grain is pubescent on the back, but the upper grain is smooth. There is a tuft of hair at the sides of the base of the lower grain, but not on the upper. The base of the lower grain is intermediate in character, and that of the upper grain is like the cultivated parent. The grain does not shatter.

Data are available from 465  $F_2$  plants, about 70 of which have been grown in the  $F_3$  generation. Observations show that *A. fatua* carries genes for gray, and possibly yellow, in addition to black. These colors segregate independently of each other and the observed ratio closely approximates the expected ratio, thus confirming Nilsson-Ehle's conclusion.

The base of the grain in *A. sativa* is dominant to that of *A. fatua* and segregates independently of color. The heterozygous condition in the lower grain can be observed in the majority of plants.

In this cross seven characters are correlated with the character of the base of *A. fatua*, as follows: Heavy awns on the lower grain, awns on the upper grain, wild base on the upper grain, pubescence on the pedicel on the lower and on the upper grain, pubescence on all sides of the lower grain, and pubescence on the base of the upper grain. The  $F_2$  generation indicates that there is a degree of linkage of the gene for pubescence on the back of the lower grain with that for black color.

The gene for pubescence on the back of the upper grain segregates independently of color, except that in the absence of the gene for pubescence on the lower grain the former is unable to act. The gene for pubescence on the back of the upper grain is linked with the wild base.

Irish potatoes in Florida, A. P. SPENCER (*Florida Sta. Bul.* 133 (1917), pp. 21-32, figs. 4).—This is a revision of Bulletin 120 (E. S. R., 30, p. 528), with brief additional notes on the prevention of frost injury through proper cultural methods, and on potato diseases and their control.

The yield and nitrogen content of soy beans as affected by inoculation, J. G. LIPMAN and A. W. BLAIR (*Soil Sci.*, 1 (1916), No. 6, pp. 579-584).—Experiments conducted at the New Jersey Experiment Stations on the relative value of 13 different commercial inoculating materials, both on an unproductive acid sandy loam soil so treated as to make the nitrogen supply the limiting factor of growth and on a fertile silt loam soil, are reported.

It is concluded "that the use of inoculating material may be very desirable in the growing of soy beans, and perhaps of other legumes. The results recorded . . . confirm results previously recorded by . . . [the] station or by other stations. It appears that where the soil is lacking in the right type of *Bacillus radicicola* inoculation is eminently desirable, and that even where the organisms are present in limited numbers the addition of larger numbers may be profitable. It appears, further, that there is a marked difference in quality of different commercial preparations for soil inoculation, and that soils derived from different sources may vary as widely as, though not more widely than, commercial cultures as to their effectiveness in promoting nitrogen fixation by legumes."

Composition of sugar beets at various stages of the growing season, H. E. ZITKOWSKI, M. P. POTVLIET, and I. W. REED (*Sugar [Chicago]*, 18 (1916), No. 6, pp. 296-298).—Considerable data are presented on the composition of the nonsugars of sugar beets, both leaves and roots, at intervals of two weeks through the growing season. The determinations included the weights of leaves and roots, the sugar content, and analyses of the dry substance and ash.

The noteworthy changes occurring in the leaves were an increase in the chlorin, sulphates, and calcium oxid, with a definite decrease in the iron and alumina oxids and carbon dioxid. Similar results were obtained in the ash of the roots, except that phosphoric acid, which had a tendency to decrease in the leaves, seemed to increase in the roots. Calcium and magnesium oxids increased appreciably, while potassium and sodium oxids remained practically constant. The total ash content per 100 parts of dry substance decreased from 20.31 to 4.15 as the beets ripened.

Sugar-cane culture for sirup production in the United States, P. A. YODER (*U. S. Dept. Agr. Bul.* 486 (1917), pp. 45, figs. 19).—The field conditions and practices and the economics of sugar-cane production in the localities where sirup is the chief product of the cane are discussed in detail.

On the basis of estimates from producers and other data, it is concluded that the price of sirup in bulk must be above 23 cts. per gallon to afford any remuneration or profit to the owner or manager. The price of sirup in the general market in recent years has ranged from 28 to 35 cts. per gallon, while in 1915 it reached 40 cts. or higher.

Recommendations are made for the utilization of the by-products, composed of leaves and tops, bagasse (pomace or mash), and the skimmings, all of which are almost entirely wasted under present practices.

Effect of rate and date of sowing on yield of winter wheat, W. M. JARDINE (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 3, pp. 163-166, fig. 1).—This paper, from the Kansas Experiment Station, discusses some investigations on the relationship of the rate of seeding to the date of seeding winter wheat. It had been observed that varying results were obtained from sowing the same rate of seed on different dates, as frequently occurs in actual farm practice. Consequently in the fall of 1912, 24  $\frac{1}{16}$ -acre plats were seeded, four at a time at

weekly intervals, at the rates of 2, 4, 6, and 8 pk. per acre, respectively, from September 16 to October 20. In 1913 and 1914 the experiments were repeated with the additional dates of September 8, October 28, and November 4. The yields of grain and straw for each date and each rate of seeding for each of the three years are given in tabular form, together with the averages for the 3-year period. The results are also shown graphically.

According to these results the 2-pk. rate of seeding produced as large yields as the 4-, 6-, or 8-pk. rates when sown before the last week in September, but after that date the heavier seeding produced larger yields on the average. This condition progresses until the 8-pk. rate, sown between the second week of October and November 1, produces nearly twice as large yields as the 2-pk. rate. The high yield of the 2-pk. rate can be explained by the heavy stooling of Turkey winter wheat when sown early in the season, while as the season advances this stooling decreases.

Field investigations have shown that it is unsafe to sow winter wheat anywhere east of the western third of Kansas earlier than September 25 in northern Kansas, and October 5 in southern Kansas, owing to the Hessian fly. It is evident, however, that such factors as rate and date of seeding must be kept in mind when efforts are being made to increase crop yields.

Wheat, yields per acre and prices, by States, 50 years 1866-1915 (*U. S. Dept. Agr. Bul. 514 (1917), pp. 16*).—Statistics are given for wheat similar to those for corn noted on page 832.

Table for converting weights of mechanical separations into percentages of the sample analyzed, E. G. BOERNER (*U. S. Dept. Agr. Bul. 516 (1916), pp. 21, figs. 2*).—The regulations under the United States Grain Standards Act provide that an original sample of shelled corn must not be less than 2 qt. in quantity and that about  $1\frac{1}{2}$  pints must be placed in an air-tight container for moisture determinations. The remainder is to be placed in a cloth bag for the determination of color, damaged corn (not including heat damage), heat-damaged corn, and foreign material and cracked corn. The maximum and minimum percentages allowed for each of these factors is specified for each grade and these percentages are to be determined by weight. To save time the 2.5-pint samples are very frequently divided into smaller samples of approximately 250 gm. and, after the mechanical separations and weighings have been made, mathematical calculations are necessary to convert these weights into percentages. A table given in this bulletin enables the analyst to compute these percentages without any calculations for percentage equivalents, ranging from 0 to 40 for samples weighing from 240 to 260 gm., inclusive. These limits cover the entire range of corn of other colors, damage, heat damage, and foreign material and cracked corn specified in the numbered Federal Corn Standards.

Directions are given for the use of the table. It is deemed essential for accuracy that considerable care be exercised in obtaining the 250-gm. sample from the 2.5 pints of the original sample and, to insure representative sampling, it is recommended that some such device as that described in Bulletin 287 (*E. S. R., 33, p. 836*) be used.

Report of the department of seed analysis, J. P. HELYAR (*New Jersey Stat. Rpt. 1915, pp. 143-150*).—The results of seed analyses for 1915 are reported and briefly discussed. Twenty per cent of the alfalfa seed examined showed the presence of Turkestan alfalfa, which, in a large number of cases, had been used as a substitute for American-grown seed.

An alien weed (*Jour. Dept. Agr. So. Aust., 19 (1916), No. 10, pp. 898-900, fig. 1*).—This is a brief note on the appearance of *Xanthium canadense* in South Australia, with directions for its eradication.

## HORTICULTURE.

[Report of horticultural investigations], M. A. BLAKE and C. H. CONNOBS (*New Jersey Stat. Rpt. 1915, pp. 37-47, 53-64, pls. 6*).—A progress report on horticultural investigations in 1915 (*E. S. R., 34, p. 143*), including also notes on the general condition of the fruit and vegetable crops in the State, records of blooming dates of various fruits, ornamental trees and shrubs at the college farm, and a list of peach types and varieties added to the plantings at the farm.

A survey of the peach trees in commercial orchards within a radius of six miles of Hammonton was made by W. N. Cowgill, in cooperation with E. Douglas, and a total of 106,025 trees were noted. Tabular data are given showing the varieties of peaches, with age and number of trees of each, together with the five most popular varieties as represented by annual plantings from 1909 to 1915. A bud sport of the Elberta peach discovered near Vineland a few years ago is here described. The tree is semidwarf and compact in its habit of growth and the foliage a much darker green in color than is the case with any other variety in the orchard. The fruit resembles Elberta in form and color, though the specimens are commonly somewhat longer and more flattened than normal Elbertas. A record is given of seedling peaches growing in the nursery as a result of crosses made in 1914. The peach trees included in this breeding work were covered with tents of cheesecloth in order to better control the process of pollinating. A brief statement is given of progress in the Vineland peach experiments. Data on this work are to be published elsewhere.

Some abnormal forms of plant growth observed during the year are here described. These include the development of adventitious buds in the base of a bloom of *Calendula officinalis*, a carnation plant bearing flowers of two colors, fasciation in the apple, superficial injury to peaches, and peculiar markings upon peaches.

During the past year or two several investigations with vegetables have been started at the station, with L. G. Schermerhorn in charge. A study of garden beet varieties conducted by W. C. Pelton is here reported. Beet seeds of various varieties were secured from several different dealers and grown with the view of comparing their various characters to determine, if possible, a basis for standardizing varieties. The study thus far made indicates that there is no uniform standard for selection among beet-seed growers, there being a notable lack of uniformity in the varietal characters of the stocks. Germination tests of 100 samples of beet seed are here tabulated.

A study of color zones in beets was made by A. Kuntz. Variation in color of the zones was observed even in the same variety (Crosby Egyptian). Generally speaking, beets with light-green foliage commonly have a large proportion of white in the root and beets with dark-red foliage a large proportion of red in the root. At least one exception to this rule was noted. Size and vigor of foliage does not appear to affect the width of the zone formation in the root and variation in the number of zones of beets of the same age seems to follow no definite rule. Beets of different ages but having the same number of leaves formed have the same number of zones, providing that number is below five. With the development of more than five zones there appears to be no regular and uniform relation between number of zones and number of leaves. Development of new zones is concentric to a central zone, the new leaves as they appear indicating the development of a new zone farther from the center.

A survey was conducted by R. W. de Baun to determine what varieties of vegetables were most popular among the commercial growers of the State. The results are presented in tabular form. The results of sweet corn suckering experiments as conducted by the same investigator show that the hills not suckered gave the heaviest yield, while the hills from which the suckers were removed late in their growth gave the smallest yield. When suckering was performed more than once the yield was still further reduced. When suckering was conducted early in the growth of the plant the corn was ready for market about three days before that of the plants not suckered. The plants suckered later in the season were slightly earlier than those not suckered.

Some preliminary experiments conducted with horseradish by the same investigator indicate that larger sized and less branched main roots may be produced for market by removing the soil and stripping off the lateral roots from the upper part of the main root sometime during the summer. The yield of marketable roots was increased also by this method. Further work to determine the financial value of the stripping method is contemplated.

[Report of heredity investigations], B. D. HALSTED (*New Jersey Stas. Rpt. 1915, pp. 262-287, pls. 13*).—A progress report on breeding work with corn, peppers, and miscellaneous plants (E. S. R., 34, p. 144).

Among the results with new  $F_1$  corn crosses, the character for floury endosperm appears to be recessive to the character for flintiness. With varieties in which the grains are normally zigzag or out of alinement this character is transmissible to the progeny of crosses with straight-rowed varieties. Selected zigzag ears from normally straight-rowed varieties do not tend to transmit the character for zigzagness when crossed with another straight-rowed variety. Observations of certain  $F_1$  crosses showed an apparent inheritance of a character for isolated or widely spaced grains.

Studies of inheritance of row-number in corn indicate that an unusually low row-number in the parental ear may be followed by a decrease in the average row-number of the offspring, as compared with that from normal seed ears. Some general observations are given on a number of  $F_2$  corn crosses. One point brought out from the preliminary observations made is the superiority of  $F_1$  selections over  $F_2$  selections, indicating the desirability of planting  $F_1$  seed for crop production. Several  $F_2$  crosses of Cuzco corn with United States field corns indicate the lack of value of Cuzco corn for breeding with local field types.

Further data are given on  $F_2$  Golden Queen-Red Cluster pepper crosses. Among the phases considered are the relations of size of plants (single leaved), size of plants (double leaved), and size of fruit, to such characters as plant length, leaf length, and position, color, flavor, and walls of the fruit; the relation between height of plant and leaf length; correlation between length of leaf and width of leaf; and correlation between the size (weight) of fruits and the size (length) of their seeds. Observations are also given on variations in size of plant, leaf arrangement, the leaf, flower, fruit position, fruit color, fruit shape and size among  $F_3$  Golden Queen-Red Cluster peppers, and on some  $F_4$  Procopp's-Cherry pepper crosses with special reference to variability in size and form of fruits.

Some new breeding work with nasturtiums, squashes and gourds, radishes, and daturas was undertaken and is here briefly considered. A study was made of abortiveness in relation to position in the pod on three crops of Mohawk bush beans. The data presented indicate that abortiveness is chiefly in the basal position and increases as the season advances.

Inheritance studies in garden plants, E. J. OWEN (*New Jersey Stas. Rpt. 1915, pp. 293-296*).—In continuation of previous work (E. S. R., 34, p. 146),

character transmission in some Scarlet Runner bean hybrids and bush bean crosses is briefly noted, and the records of breeding experiments with eggplants, okra, and Hibiscus, as well as the limitation studies with beans and peas, are presented in tabular form.

The results of five seasons' work with beans indicate that limiting the yield of the plant to one pod greatly increases the weight of the seed.

Truck crops, W. J. GREEN and E. J. RIGGS (*Ohio Sta. Bul. 303 (1916), pp. 177-184, figs. 4*).—An outline is given of investigations of the Washington County truck farm, including the results of fertilizer experiments with sweet corn, cucumbers, cabbage, and tomatoes as determined by increased yield per acre under each treatment.

The results for the first season show that the crops grown on manured land have not been any larger than those on the land receiving chemical fertilizers, and that manure valued at \$2 per ton has been a costly fertilizer as far as the first crop is concerned. It is pointed out, however, that a larger part of the effect of manure is realized in the succeeding crops than is the case with chemical fertilizers.

A chemical study of the asparagus plant, F. W. MORSE (*Massachusetts Sta. Bul. 171 (1916), pp. 265-296*).—In connection with a long-continued series of fertilizer experiments on asparagus conducted at the station (E. S. R., 26, p. 44), the author investigated the chemical composition of the asparagus plant and the effect of different fertilizers upon the proportions of the more important plant constituents. The analytical data secured are presented in detail and fully discussed. See also previous papers (E. S. R., 30, p. 142).

As to the chemical composition and changes during different stages in the development of the asparagus plant, "during the earlier years of the asparagus field the crowns and roots steadily increased in size, doubling in weight between the second and fourth years after setting. The proportion of protein remained nearly constant in the dry matter of the roots during the period observed, while the sugar decreased and the cellulose and allied compounds increased. The composition of the young stalks cut in the spring changed as the cutting season advanced. Dry matter was practically constant, but sugar increased in proportion while protein decreased somewhat.

"The development of the asparagus tops to maturity was accompanied by a continuous increase in the cellulose and its related groups—pentosans and lignin. Protein and sugar decreased in their proportions, but were not wholly translocated to the roots from the ripened tops. Water was the dominant constituent of the asparagus plant in all the stages studied. It was highest in the young stalks. The summer or growing roots were a little more watery than the late fall or storage roots. Calcium oxid and sulphuric acid steadily accumulated in the asparagus tops as they grew old, but potash and phosphoric acid were transferred either to the fruit or back to the roots."

Relative to the effect of different fertilizers on the composition of the asparagus plant, it was found that "withholding one of the constituents of a complete fertilizer from the annual top-dressing was accompanied by a smaller average weight of roots in the samples taken from the plot thus treated. Withholding nitrate of soda lessened the percentage of nitrogen and of soda in the roots; withholding muriate of potash lessened the proportion of potash in the roots; withholding acid phosphate produced no apparent change in the constituents of the roots. An increase of nitrate of soda from the minimum to the medium amount in the top-dressing caused an increase in the percentage of nitrogen in the dry matter of the roots. An increase in the amount of muriate of potash produced some increase in the percentage of potash in the roots.

"Asparagus roots taken from plats receiving the nitrate of soda in the spring were noticeably heavier in weight and a little poorer in nitrogen than roots from plats that were top-dressed with nitrate in the summer. During the cutting season the production of young stalks drew most heavily on the sugar contained in the roots, but there was no approach to exhaustion of that constituent. Fully twice as much sugar was consumed as would have been required to produce the carbonaceous matter in the young stalks. The roots apparently absorbed nitrogen, lime, and sulphuric acid during the cutting season. Potash and phosphoric acid were apparently supplied to the young stalks wholly from the reserves in the roots."

From the standpoint of cultural practice the chemical study has shown that a complete fertilizer rich in nitrogen is required in generous amounts in order to produce a continuous strong development of the asparagus plant. The physiological need of water, together with the sandy quality of most asparagus soils, indicate that irrigation would be advantageous, if not necessary, for the production of maximum crops. The reserve material stored in autumn in the roots was found to be principally sugars.

"Destruction of the tops by rust, or their premature removal to be rid of the berries, must lessen the amount of sugar which can be stored in the roots. The fertilizing constituents which were stored in the roots over winter appeared to be nearly, if not quite, sufficient for the full development of the succeeding spring crop. There was evidence of a small intake of nitrogen during the cropping season and a pronounced absorption of lime and sulphuric acid. Sulphuric acid was found to be equally, if not more, important than phosphoric acid among the constituents of the asparagus plant. Nevertheless, the sulphate of lime in the acid phosphate appeared to suffice fully for the needs of the crop."

**Connecticut Valley onion supply and distribution**, A. E. CANCE, W. L. MACHMER, and F. W. READ (*Massachusetts Sta. Bul. 169 (1916)*, pp. 49-122, figs. 40).—A study of onion supply and distribution in the Connecticut Valley, including introductory considerations relative to onion supply, regions of production, and shipping periods in the United States as a whole. In part 1 the Connecticut Valley onion district is considered with reference to topographic features, onion soils, general marketing facilities, general history of onion growing in Massachusetts, economics of production, tenure of land, soils and climatic conditions, extent of industry, methods of culture, seed and sets, varieties, weeding, economic factors, harvesting, cost of production, and yields.

Part 2 discusses in detail marketing the crop, methods of sale, storage of onions, transportation of onions, problems of transportation, and prices of onions.

As a result of the investigation the authors present a number of recommendations suggesting improved methods of harvesting and marketing.

**Root hardiness of fruit trees** (*Wisconsin Sta. Bul. 275 (1917)*, pp. 34, 35).—As here briefly summarized the studies of root hardiness being conducted at the station have shown thus far that little injury occurs at 21° F. When the temperature falls to 14° the cambium tissue is generally injured. Data on the influence of cover crops on the moisture content and temperature of the soil as a factor in root hardiness indicate that cover crops are chiefly of value in holding the snow, which has proved to be the best protection of the root system.

Observations on the production of scion roots have been made on about 6,000 nursery trees. It appears doubtful whether apple trees produce sufficient scion roots, in a nursery at least, to support the tree in case the stock roots are winterkilled. The results thus far accumulated do not accord with the view sometimes advanced that winterkilling is largely due to desiccation of injured parts.

The cost of producing apples in western Colorado, S. M. THOMSON and G. H. MILLER (*U. S. Dept. Agr. Bul. 500 (1917), pp. 44, pls. 2, figs. 10*).—This is the second of a series of bulletins giving information relative to different methods of orchard management and the cost of apple production in different apple-growing districts (*E. S. R., 36, p. 443*). The present bulletin reports a detailed study made in 1914–15 of the current cost factors involved in the maintenance of orchards and the handling of the crop on 125 farms in the fruit region of Mesa, Delta, and Montrose counties, Colo.

The total cost of producing apples for the 125 farms represented averaged 84.4 cts. per box. Labor cost averaged 39.4 cts. per box and \$111.88 per acre. Material and fixed costs averaged 45 cts. per box and \$127.91 per acre. The average yield for the district was 284 boxes per acre. The trees in the orchards studied averaged 17 years of age and 74 to the acre. The average total investment per acre of apple orchard was \$751.56. Jonathan was the leading variety, with Ben Davis, Rome Beauty, Gano, and Winesap following, each of about equal importance.

With the investigation as a basis the authors make suggestions relative to improvements in orchard management practice.

The cost of producing apples in Hood River Valley, S. M. THOMSON and G. H. MILLER (*U. S. Dept. Agr. Bul. 518 (1917), pp. 52, pls. 4, figs. 14*).—This is the third bulletin of the above-noted series and comprises a report of a detailed study made in 1915 of the current cost factors involved in the maintenance of orchards and the handling of the crop on 54 farms in the Hood River Valley.

In this region the total cost of apple production for the 54 bearing orchards averaged \$1.02 per box and \$222.83 per acre for orchards under clean cultivation and \$232.32 per acre under mulch crops. The average cost per box exclusive of interest on orchard-land investment was 66.4 cts. Net labor costs averaged 38.3 cts. per box. Material and fixed costs constituted 62.5 per cent of the total cost. The trees in the orchards studied averaged 12 years of age and 72 trees to the acre. The average total investment per acre of apple orchard was \$990.74; the average yield, 222 boxes per acre. The Hood River Valley appears to be particularly well adapted to the production of Yellow Newtown and Esopus apples, both of which grow to perfection there. Based on results of this study suggestions are given relative to local problems of orchard management.

The mulched-basin system of irrigated citrus culture and its bearing on the control of mottle-leaf, L. J. BRIGGS, C. A. JENSEN, and J. W. MCLANE (*U. S. Dept. Agr. Bul. 499 (1917), pp. 31, pl. 1*).—The work carried out by the authors in 1914 (*E. S. R., 35, p. 754*) showed that one-half of the mottling of orange leaves in about 120 orange groves investigated was associated with a low humus content of the soil. Evidence was secured in this work which indicated that inadequate irrigation might be responsible in part for the development of mottle-leaf. The present paper reports field experiments relating to the irrigation of oranges and the use of organic fertilizers in relation to mottle-leaf. It deals particularly with a new method of citrus culture, the "mulched-basin system," in which low dikes are thrown up so as to form large shallow irrigation basins near each tree and each basin is heavily mulched with alfalfa hay, bean straw, manure, or some other organic material.

In the experiments thus far conducted the mulched-basin system conserved soil moisture better than any other system of soil treatment compared with it and none of the basined trees on either light or heavy soils wilted. Under all the other cultural methods employed wilting occurred at some period during the summer on both light and heavy soils.

The new leaf growth on the basined trees was less mottled than the new leaf growth on the unbasined trees after sufficient time had elapsed for the

mulched-basin system to produce response in the tree growth. The new leaves on the basined trees were larger and darker in color and had a better texture than those on the unbasined trees, especially on heavy soil. Likewise, the new growth of rootlets was better under the mulch in the basins, and the quality of the fruit on the basined trees was superior to that of the unbasined trees.

The experiments indicate that alfalfa and bean straw are superior to stable manure for mulching purposes. In addition to producing a measurable increase in the humus content of the soils, the use of an organic mulch moderates the rise in soil temperature during the day and aids in conserving moisture.

The authors suggest that surface mulching with organic material, especially when available in quantities sufficient to cover the entire surface, may in the long run prove fully as effective as the use of the mulching material in basins. The mulched basin, however, brings about the incorporation of humus more quickly than organic mulches with furrow irrigation, and it also appears to be the most effective means of using a limited quantity of mulching material.

In view of the successful results in the experimental tracts the mulched-basin system is recommended for experimental consideration by citrus growers as compared with other systems in commercial practice.

The mulch basin system, L. J. BRIGGS, C. A. JENSEN, and J. W. McLANE (*Cal. Citrogr.*, 2 (1917), No. 5, pp. 11, 12, fig. 1).—A summary of the above.

A humidifier for lemon curing rooms, A. D. SHAMEL (*U. S. Dept. Agr. Bul. 494* (1917), pp. 10, figs. 7).—This bulletin describes the plan of work used in conducting humidity studies in some lemon-curing rooms in southern California, summarizes the results noted in a previous paper (*E. S. R.*, 36, p. 741), and describes and illustrates the arrangement and structure of a humidifier invented by the author in 1914 for use in maintaining conditions of uniform humidity in lemon-curing rooms.

The humidifier has been successfully used for two seasons, both for controlling humidity in lemon-curing rooms and for improving air conditions in living rooms in private houses and elsewhere in California.

Shade trees, characteristics, adaptation, diseases, and care, G. E. STONE (*Massachusetts Sta. Bul. 170* (1916), pp. 123-264, figs. 110).—A practical treatise covering the various questions relative to shade trees and their management and superseding Bulletin 125, previously noted (*E. S. R.*, 20, p. 643), which took up the subject in a general way.

The phases discussed include requirements of shade trees; street and roadside trees; what shall we plant; rapidity of growth of trees; streets and avenues; distance to plant; country roadsides; root characteristics; branching characteristics; soil conditions, texture, etc.; soil covers, lawns, macadam, etc.; excavations, curbing, and sidewalks; effects of light and shade; transplanting; tree surgery; tree guards; fertilizing trees; diseases of trees; winter injuries; drought; sun scorch and bronzing of leaves; mechanical injuries; injurious chemical substances; effects of illuminating gas on trees; effects of atmospheric gases on vegetation; electrical injuries; the spraying of shade trees; valuation of shade trees; court decisions concerning damages to trees; and codified shade tree laws of Massachusetts, 1915.

Fumigation of ornamental greenhouse plants with hydrocyanic acid gas, E. R. SASSCER and A. D. BORDEN (*U. S. Dept. Agr. Bul. 513* (1917), pp. 20, figs. 4).—Practical directions are given for fumigating greenhouse plants with hydrocyanic acid gas, including a discussion of the necessary equipment, method of preparing the house and of computing the cubical contents of greenhouses, time for fumigation, chemicals required, methods of mixing the chemicals and

generating gas, ventilation after fumigation, effects of weather conditions on fumigation, the advisability of a fumigation box, cost of fumigation, and precautions. Tables are given showing a large number of ornamentals, including a few tropical and subtropical plants, that have been fumigated by the authors either in greenhouses or in fumigation boxes. The data given include the name of the plant, rate of application, exposure, house temperature, infestation, and results on both plants and insects. The results are for the most part based on the fumigation of commercial houses under commercial conditions.

### FORESTRY.

**A forest census of Alabama by geographical divisions**, R. M. HARPER (*Geol. Survey Ala. Monograph 8, Sup. (1916), pp. 208-214, fig. 1*).—This paper, which is supplementary to a previous geographical report on Alabama forests (E. S. R., 29, p. 746), has been noted from another source (E. S. R., 35, p. 748).

**Thirteenth annual report of the state forester [of Massachusetts]**, F. W. RANE (*Ann. Rpt. State Forester Mass., 13 (1916), pp. 124, pls. 6*).—This is the usual annual report relative to the administration and management of the state nurseries and forests in Massachusetts, including also accounts of reforestation work, private cooperative forestry work, utilization of forest products, and fire protection work. Information is also given relative to the present status of the chestnut blight and white pine blister rust and the work of suppressing the gipsy and brown-tail moths.

**The present and future of Pennsylvania's forests**, S. B. ELLIOTT (*Dubois, Penn.: The Penn. Conserv. Assoc., 1916, pp. 28, pls. 6*).—A summary of the past and present conditions of Pennsylvania forests, together with measures suggested for their restoration and perpetuation.

**Tree planting on agricultural estates and roads**, T. W. BROWN (*Min. Agr. Egypt, Hort. Sect. Leaflet 11 (1917), pp. 65, pls. 8*).—In addition to directions for planting and growing trees descriptions are given of trees found in Egypt.

**The Central Provinces forest manual (Nagpur, India: Govt., 1915, 3. ed., pp. XIII+331)**.—A manual on the administration of the state forests in the Central Provinces of India. Part 1 deals with the Indian forest act of 1878 and its application. The succeeding parts deal with the organization of the forest department, constitution of forests, management and working of the forests, and office business.

**Note on an inquiry by the government of India into the relation between forests and atmospheric and soil moisture, in India**, M. HILL (*[Indian] Forest Bul. 33 (1916), pp. 41, pls. 2*).—This paper summarizes the results of inquiries conducted throughout the Provinces of India since 1906.

Such evidence as is available in India points to the conclusion that the influence of forests probably tends to increase the rainfall, but not in any marked degree. Thus far no satisfactory data have been secured warranting any definite conclusion relative to the influence of forests on the level of the underground water table. In most of the Provinces no serious damage to the flow of rivers had taken place and no great injury had been done to cultivation due to forest denudation. There were several local exceptions to this conclusion in the Punjab, in Bengal, and to a less extent in eastern Bengal and Assam.

**Seed selection in the cultivation of Hevea brasiliensis**, C. BEADLE and H. P. STEVENS (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 1 (1917), pp. 19-24*).—In this paper the authors outline a method of procedure for carrying on seed selection investigations with Para rubber.

Ecology of sal (*Shorea robusta*).—III, Soil aeration and water cultures, R. S. HOLE and PURAN SINGH (*Indian Forest Rec.*, 5, (1916), No. 4 [pt. 3], pp. 87-102, pls. 4).—Further experiments relative to the causes of the dying out of sal seedlings (E. S. R., 36, p. 345) led to the conclusion that inferior growth in badly aerated soil is correlated with an accumulation of carbon dioxide or a deficiency of oxygen in the soil, and that poor growth is not due to the presence of excessive water in itself. See also previous notes (E. S. R., 35, p. 649; 36, p. 44).

Our wattles, T. C. WOLLASTON (*Melbourne and Sydney: Lothian Book Publishing Co.*, [1917], pp. 76, pls. 12).—Popular descriptive accounts with illustrations of the Australian wattles (*Acacia* spp.).

Investigations of the rotting of slash in Arkansas, W. H. LONG (*U. S. Dept. Agr. Bul.* 496 (1917), pp. 14).—This bulletin reports an investigation of the rapidity with which timber slash or brush rots and of the fungi causing this rotting under each of the methods of pulling, piling, and scattering brush.

When brush is lopped and scattered it rots much more rapidly than when either piled or pulled. None of the main fungi concerned in rotting either oak or pine slash in Arkansas produce heart rots in living trees.

Yields from the destructive distillation of certain hardwoods, II, R. C. PALMER (*U. S. Dept. Agr. Bul.* 508 (1917), pp. 8, figs. 2).—In continuation of a previous report giving the yields from the destructive distillation of a number of hardwoods and of material from different parts of the tree (E. S. R., 32, p. 48) the present bulletin gives the yields for white elm, slippery elm, silver maple, green ash, blue ash, yellow ash, chestnut oak, tanbark oak, California black oak, Louisiana swamp oak, and eucalyptus. The results are deemed of especial interest to the manufacturers of by-products.

Poles purchased, 1915, A. M. MCCREIGHT (*U. S. Dept. Agr. Bul.* 519 (1917), pp. 4).—A statistical account of the number of poles purchased during 1915 in the United States by the telephone and telegraph companies, steam and electric railroads, and electric light, heat, and power companies. A total of 4,077,964 poles was reported as purchased during 1915, an increase of 659,944 over 1911, and the largest number reported in any single year.

Handbook on wood preservation ([*Baltimore, Md.*]: *Amer. Wood-Preservers' Assoc.*, 1916, pp. V+73).—A compilation of facts and figures relative to wood preservation. The following subjects are considered: Decay, preparation, and treatment of wood; chronicle of wood preservation; progress in wood preservation; processes for preserving wood; wood preservatives; manufacturers of wood preservatives and wood-preserving equipment; uses and users of preserved wood; wood-preserving plants; American Wood-Preservers' Association; and a bibliography of wood preservation.

## DISEASES OF PLANTS.

Transmission of diseases by seeds, L. BLARINGHEM (*Assoc. Franc. Avanc. Sci., Compt. Rend.*, 43 (1914), pp. 470-478, fig. 1).—The author, concluding a discussion of investigations and observations on the transmission of plant diseases and their reappearance, states that there probably exist different varieties of *Althæa rosea* as regards the period of sporulation of *Puccinia* parasitic thereon. The facts are emphasized that the more obvious stages of disease fungi are not necessarily those in which the disease is transmitted (citing the case of a mycoplasmic stage or one in which seeds, though infected, do not reveal that fact to the eye), and that the duration of the stages of latency or of activity (knowledge of which is necessary to the control of disease) is dominated largely by external conditions. It is thought that the apparent formation of resistant

strains may be the result of the loss of the parasite, giving rise to varieties by a process analogous to regressive mutation, or it may result from the influence of prolonged or severe climatic factors, the parasite in such cases being simply latent during successive generations.

**Chemotropic reactions in *Rhizopus nigricans*, A. H. GRAVES** (*Mem. N. Y. Bot. Gard.*, 6 (1916), pp. 323-331; *Bot. Gaz.*, 62 (1916), No. 5, pp. 337-369, figs. 4).—A study of several fungi, mainly *R. nigricans*, has demonstrated a negative chemotropism of the fungi toward their own metabolic products. A much weaker positive chemotropism toward such substances as cane sugar and glucose was noted. This positive response is better in case of turnip juice and may in general be better in plant juices. The facts as noted suggest that the distribution of a parasitic fungus in a plant may be due more to negative chemotropism in regard to its own staling products than to positive chemotropic stimulation.

**Discovery of internal telia produced by a species of *Cronartium*, R. H. COLLEY** (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 9, pp. 329-332, pl. 1).—The author reports the production of internal telia by *C. ribicola* in the petioles of leaves of species of *Ribes*. Internal rust sori, four types of which have been found developing in the host plant tissue, are regarded as rather common teratological phenomena.

**Discussion of certain plant diseases, J. T. BARRETT** (*Proc. Fruit Growers' Conv. Cal.*, 47 (1915), pp. 216-222).—The participants in this discussion dealt with prune rust (*Puccinia pruni*), two epidemics of which have occurred in southern California in the last two years; apricot scab or black spot, which was serious in at least two sections during the previous year; shot hole, easily confused with scab, but readily controlled with Bordeaux mixture; and brown rot, which is now under investigation.

**Report of the department of plant pathology, M. T. COOK ET AL.** (*New Jersey Stas. Rpt. 1915*, pp. 365-374).—In these pages a report is given of the activities of the department in 1915, with a list of the common diseases observed during that time.

[Investigations on plant diseases] (*Wisconsin Sta. Bul. 275* (1917), pp. 35-40, figs. 3).—Progress accounts are given of investigations of various plant diseases carried on at the station.

In continuation of the work on tobacco diseases, J. Johnson is reported to have carried on studies of inheritance in crosses between resistant and susceptible varieties of tobacco and also of the distribution of the causal organism of tobacco root rot (*Thielavia basicola*). In the latter investigation, he is said to have found 66 new hosts for this fungus.

In studies of inheritance of disease resistance in plants, W. H. Tisdale is investigating wilt resistance in flax and also strains of cabbage resistant to yellows. Resistance to wilt is considered a dominant characteristic in flax, while in case of cabbage resistant to yellows, a greater degree of variability in first generation seed was observed than in case of flax resistant to wilt.

A brief account is given of a bacterial disease of barley, a preliminary note of which has already been given (*E. S. R.*, 35, p. 845).

For the control of barley diseases through seed disinfection, A. G. Johnson reports the successful use of formaldehyde for all of the three important barley diseases, stripe, loose smut, and covered smut, a preliminary account of his investigations having been previously noted (*E. S. R.*, 36, p. 247). In general practice, he recommends controlling the stripe disease by soaking seed for two or three hours in 1 pint of formaldehyde to 20 gal. of water.

The work of G. W. Keitt on the control of cherry leaf spot is briefly outlined, attention being called to the successful use of Bordeaux mixture or lime-sulphur against this disease (*E. S. R.*, 36, p. 149).

[Plant diseases in British Guiana], C. K. BANCROFT (*Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, App. 2, p. 13*).—In the annual report on scientific investigations in the botanic gardens during 1914-15, the author states that the principal diseases affecting imported sugar cane during the year were the leaf spot (*Leptosphaeria sacchari*) and leaf sheath spot *Cercospora vaginæ*. Other cane diseases mentioned are the root, or dry disease (*Marasmius sacchari*) and two rind diseases caused respectively by *Trichosphaeria sacchari* and *Melanconium sacchari*.

Coconut bud rot, apparently associated with defective drainage or other adverse soil conditions, continued to be prevalent in some localities. Witches' broom disease of cacao has proved to be amenable to treatment by pruning and spraying.

Two new root diseases appeared on one lime plantation, due respectively to *Fomes semitostus* and *Hymenochaete noxia*. Citrus knot was reported from the same plantation. The causation has not been determined, though it may be due to attacks of bird vine (*Loranthus theobromæ*).

Coffee anthracnose (*Colletotrichum* sp.) was largely controlled by repeated spraying with Bordeaux mixture and the destruction of affected leaves and fruits.

The leaf disease of Para rubber mentioned in the report of the previous year (E. S. R., 34, p. 442) has done considerable damage.

Blast of rice, due to *Piricularia oryzae*, is recorded for the first time, but it is probably not yet widely prevalent.

[Plant diseases in Tasmania], H. M. NICHOLLS (*Agr. and Stock Dept. Tasmania, Rpt. 1915-16, pp. 18-20*).—The annual report of the government microbiologist, besides mentioning some insect pests of plants, gives a brief account of *Armillaria mellea*, causing damage to young apple orchards and apparently benefited by the use of potassium permanganate, picric acid, and iron sulphate on the roots. A Septogloeum, supposed to cause a disease of field peas; *Fusarium oxysporum*, causing wilt disease of potato; Irish blight in some sections; a *Fusarium* causing leaf wilt and the speedy death of young fruit trees, particularly apple; *Valsa prunastri* and *V. ambiens*, usually on apple trees killed by *Fusarium*; and mildew of cereals (*Erysiphe graminis*) are also noted. Experiments for the prevention of brown fleck of potatoes are still in progress.

A physiological study of two strains of *Fusarium* in their causal relation to tuber rot and wilt of potato, G. K. K. LINK (*Nebraska Sta. Research Bul. 9 (1916), pp. 3-45, figs. 13; Bot. Gaz., 62 (1916), No. 3, pp. 169-209, figs. 13*).—An investigation was made of two species of *Fusarium* occurring on the potato to determine whether there is a sharp biological contrast between the species, as claimed by Wollenweber (E. S. R., 29, p. 444), and if so, to what physiological basis this contrast is to be attributed. As a result of his studies, the author concludes that there is not so sharp a contrast as would be expected from the paper cited.

A detailed account is given of the ecology and physiology of the organisms causing tuber rot and wilt of potato, and it is reported that *F. tuberivorum* (E. S. R., 29, p. 47) and *F. trichothecioides* (E. S. R., 27, p. 650) are identical. Studies of this species and *F. oxysporum* showed that both can produce tuber rot and wilt of the potato plant. Wilt is induced by the destruction of the root system and by clogging the xylem elements in the stem. In mild cases it is characterized by discoloration, curling and rolling of the leaves, production of aerial tubers, etc. Under field and storage conditions *F. oxysporum* is probably more responsible for wilt than is *F. trichothecioides*, while the latter is more responsible for tuber rotting. The biological characters of the different species are described at length.

On the part played by the seed in the dissemination of potato diseases and on the advantages of disinfecting with corrosive sublimate, H. M. QUANJER (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch.* [Wageningen], 9 (1916), No. 2-4, pp. 94-126, pl. 1).—This is the second contribution to a monograph on potato disease in Holland (E. S. R., 29, p. 347). The quarantine measures employed in the United States are said to have made it necessary to study closely the so-called scab diseases from the standpoint of their distribution and control in Holland.

Common scab (*Actinomyces scabies*) is said to be present in many parts of that country, the fungus being visible for only a little while just after digging as a gray film on the scab spots. In cases where spraying with Bordeaux mixture has retarded the ripening process, the scab spots are deeper and more numerous than when the potatoes are ripened and dug earlier. Powdery scab (*Spongospora subterranea*), though not so widely distributed, is present in many parts of the Netherlands. The canker form is not known in that country. *Hypochnus solani* (*Rhizoctonia solani*) is very common on the tubers, by which it can be transmitted.

Experiments were made testing the protective value for each phase of scab of a 1:1,500 corrosive sublimate solution on low clay land not infected, on high sandy soil infected with *A. scabies* and *R. solani*, and a peaty soil infected with all three diseases, the tabulated results showing the yield of infected or sound tubers and the increase in market value by treatment. It is thought that a 1:1,000 corrosive sublimate solution is preferable (see also below).

On the nature, mode of dissemination, and control of phloëm necrosis (leaf roll) and related diseases, H. M. QUANJER, H. A. A. VAN DER LEK, and J. O. BOTJES (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch.* [Wageningen], 10 (1916), pp. 1-162, pls. 12; abs. in *Gard. Chron.*, 3. ser., 60 (1916), No. 1550, p. 124). This is the third contribution of the series noted above. It deals with the external and the histological features, and the pseudo-hereditary character of leaf roll and with metabolism in the plants affected therewith, the causation, communicability, external influences, prevention, and notes on diseases related to or comparable with leaf roll of potato or other plants, such as potato mosaic and curly dwarf, yellow stripe and sereh of sugar cane, leaf curl of peanut (*Arachis hypogæa*), curly top and mosaic of sugar beet, and cases of infectious chlorosis in various plants.

The phloëm in affected plants shows characteristic changes, which are described and which are summed up in the term necrosis. Apparently it is transmitted by the mother tubers, by grafting sound on affected plants, and vice versa, and it passes into the soil, which remains capable of infecting potato plants for at least two years. Varieties differ in susceptibility. The infecting organism has not yet been discovered and may be ultramicroscopic. The disease is apparently not due primarily to the condition of the plant.

Report of potato spraying experiments for 1915, H. C. LINT (*New Jersey Stas. Rpt. 1915*, pp. 381-394, pl. 1).—Results of cooperative experiments with various fungicides and insecticides for the control of potato diseases and insect pests are given which show that Bordeaux mixture applied to an early crop of potatoes increases the yield. Basing his conclusions on three years' experiments, the author considers that climatic conditions play an important rôle in deciding to what extent the benefits from Bordeaux mixture will be realized. Both homemade and commercial preparations of Bordeaux mixture were found to prolong the life of the vines and to give an average increase of about 45 bu. per acre when applied to second crop potatoes. Early blight is said to have been very prevalent in the plots of the second crop experiment, and it is probable that the control of this disease may account for much of the increase in

yield due to Bordeaux spraying. Bordeaux mixture gave the best control of flea beetles of any of the mixtures applied. Sulphur dust mixtures were somewhat beneficial, but their effectiveness as compared with Bordeaux mixture has not been definitely established. The state of cultivation and the fertility of the field are considered to have an intimate relation to the benefit to be derived from spraying.

**Report of potato scab experiments, 1915, H. C. LINT** (*New Jersey Stat. Rpt. 1915, pp. 375-381, fig. 1*).—In continuation of previous accounts of the use of sulphur for the prevention of potato scab (E. S. R., 34, p. 155), the author gives the results of further tests to determine the value of sulphur in connection with the control of this disease.

Experiments carried on in a number of localities indicate that in some cases broadcasting the sulphur is more effective than mixing it with fertilizers. In one instance the mixture of sulphur with fertilizers caused considerable injury to the tubers. In another experiment an increased yield was obtained where sulphur was employed. Sulphur was again found to be more effective in combination with potassium chlorid than with potassium sulphate and with acid phosphate than with steamed bone.

In connection with seed treatment with formaldehyde and corrosive sublimate, sulphur was found more effective in controlling scab when used with treated than with nontreated seed. A study of the effect of sulphur applications on succeeding crops showed that no permanent injury to hay crops resulted, and a beneficial effect was observed on potato crops grown on the same land. Two successive applications of 300 lbs. appear to be more effective than one of 600 lbs., and as effective as one of 600 lbs. followed by 300 lbs.

**Physiological studies of *Bacillus radicicola* of soy bean (*Soja max*) and of factors influencing nodule production, J. K. WILSON** (*New York Cornell Sta. Bul. 386 (1917), pp. 367-413, figs. 15*).—The experiments described in this bulletin were undertaken to study the physiology of the causal organism of nodule formation on soy beans and the factors influencing nodule development, the work being carried on in the greenhouse and laboratory. The data obtained are considered to apply to this organism only, although in many respects they agree with those obtained by other investigators working with other strains of *B. radicicola*.

It was found that nodule formation can be checked or stimulated depending on the presence or absence of certain salts and the amount of moisture present. Among the compounds found to stimulate nodule formation are the chlorids, phosphates, calcium-containing compounds, and certain organic carbon-containing compounds, while nitrates, ammonia-containing or ammonia-producing compounds, and sulphates reduced nodule production. In the experiments, an increase in moisture content from 35 to 45 per cent more than doubled the production of nodules, while with an increase from 45 to 55 per cent, it was nearly doubled. The composition of the soil solution is considered an important factor in controlling nodule production.

It is thought that the failure of pure culture work may possibly be explained by the application as fertilizers of inhibiting substances.

A bibliography is appended.

**A squash disease caused by *Choanephora cucurbitarum*, F. A. WOLF** (*U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 9, pp. 319-328, pls. 3*).—In an investigation carried on at the North Carolina Experiment Station, the author found summer squashes attacked by a phycomycetous fungus, *C. cucurbitarum*. A study has been made of the development of the disease and the morphology of the causal organism, the results of which are given in some detail.

The organism was found parasitic on summer squashes, causing a blight of the flowers and a rot of the fruits. The disease has been the cause of very considerable losses. The infection of the fruit is said to occur for the most part by the passage of the fungus from the fading corolla to the young squash. In addition, it is believed that various species of bees and striped and spotted cucumber beetles play some part in disseminating the disease. The fungus has also been found on the flowers of cucumber, althea, okra, cotton, and other malvaceous plants.

**Arsenical injury through the bark of fruit trees**, D. B. SWINGLE and H. E. MORRIS (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 8, pp. 283-318, pls. 6).—The authors report a series of investigations carried on at the Montana Experiment Station to determine the possibility of arsenical injury to sprayed fruit trees and the conditions under which injury would occur. Trees were treated with a number of arsenical compounds, the application being made to branches of various sizes, trunks, crowns, and roots.

As a result of their investigations, the authors claim to have established conclusively that arsenical compounds used as insecticides can be made to injure the crowns of trees under conditions very similar to those that result from some orchard practices. It was found that the periderm on the smooth bark of apple trees is practically impervious to arsenical solutions, but that such solutions may be admitted through wounds, lenticels, or latent buds, in which case more or less injury will follow. As the trees become older and the bark rougher the cracks made in its production will admit arsenical solutions to the inner tissues, which will be injured. Roots and branches of equal size and with similar bark are about equally susceptible to arsenical injury. If the injury is rapid, very definite longitudinal streaks will be produced in the bark and sapwood, but if the injury is slow, the streaking is not so evident. Paint applied to fresh wounds offers a partial but not complete protection. The injury caused by arsenical compounds is not necessarily due to impurities they may contain.

**Diseases of deciduous fruit trees**, R. E. SMITH (*Proc. Fruit Growers' Conv. Cal.*, 47 (1915), pp. 257-263).—This includes a discussion of gummosis as an expression of injury, of bad cultural conditions, or of various causes more or less unfavorable to the health of the tree. It also deals with pear blight and its variability and control by vigilance and careful early pruning.

**Peach yellows and little peach at Vineland**, M. A. BLAKE and C. H. CONNORS (*New Jersey Stas. Rpt. 1915*, pp. 51-53, pls. 2).—A report is given of observations regarding peach yellows and little peach on the peach orchards established at Vineland (E. S. R., 20, p. 1037), one having been planted in 1907, another in 1908, and a third in 1912. From the different orchards, 5.5, 11.8, and 0.8 per cent of the trees, respectively, have been killed by the diseases in question. No varietal difference as to susceptibility to these diseases has been noted. The authors recommend that trees be removed as soon as symptoms of either disease appear. In the experimental orchards no tree planted in a position from which a diseased tree had been removed failed to grow and no replanted tree has become diseased.

**Plum pockets**, E. RABATÉ (*Vie Agr. et Rurale*, 6 (1916), No. 22, pp. 388-391, figs. 7).—Briefly discussing plum pockets caused by *Eoxascus pruni*, the author recommends the removal and destruction of all diseased fruits, and the disinfection of the tree in January with a solution containing 10 per cent of iron sulphate and 2 per cent of copper sulphate, repeating the disinfection after blooming occurs.

**Little leaf of the vine**, F. T. BIOLETTI and L. BONNET (*U. S. Dept. Agr., Jour. Agr. Research*, 8 (1917), No. 10, pp. 381-398, pls. 4, figs. 2).—In a contribution from the California Experiment Station the authors describe a disease of

the vine variously known as little leaf, curly leaf, and yellow leaf. This disease is known to have been present in California for a number of years, although no printed reference to it has been found that points clearly to its occurrence before 1900. At the present time, it is said to attack vines in various regions from the borders of Sacramento and San Joaquin Counties to the southerly end of the San Joaquin Valley. In seriousness it is to be compared with *Oidium* and *Phylloxera*.

Affected vines show small, yellowish leaves, short jointed canes, and in severe cases, dead spots on the leaves and gummy secretions in the conducting tissues of the arms and trunks. In severe cases the vines die after a few years. No parasite has been found connected with the disease, and all the evidence seems to show that it is not infectious. The trouble is believed to be associated with local conditions of soil, water, and temperature. No effective method of treatment has been demonstrated, although the application of gypsum to the soil is said to have given promising results.

**Control of *Oidium* or vine mildew, F. T. BIOLETTI** (*Proc. Fruit Growers' Conv. Cal.*, 47 (1915), pp. 147-154).—This is a paper by the author with the discussion thereon.

It is stated that during 1915 attacks of *Oidium* have been exceptionally widespread and destructive. The damage was particularly intense in the interior and in regions where it is usually mild or unknown, rather than in those sections where it is always present. The unusual severity this year is ascribed to weather conditions. Finely powdered sulphur, applied while the leaves are dry, is recommended. Winter treatments are believed to be ineffective.

**The spraying of yellow pineapple plants on manganese soils with iron sulphate solutions, M. O. JOHNSON** (*Hawaii Sta. Press Bul.* 51 (1916), pp. 11, figs. 4).—The yellowing of pineapples on the black manganese soils of the island of Oahu is said to present a serious problem. Previous work of the station (E. S. R., 27, p. 129) had shown that this yellowing is correlated with the presence of abnormally large quantities of manganese in the soils.

The author gives an account of experiments for the control of the pineapple yellows by spraying the plants with an 8 per cent solution of iron sulphate. This can be done at a cost for each application of approximately 60 cts. per acre. In a field trial, the rows sprayed with the iron sulphate solution produced more than double the weight of fruit produced by the check rows, while a still greater increase was noted in the proportion of first-grade fruits.

As a result of his investigations, the author recommends spraying plants with the solution described above when there are any indications of yellowing, repeating the spraying often enough to keep the plants in a green and healthy condition.

**Citrus canker investigations at the Singalong Experiment Station, E. D. DORRYLAND** (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 2, pp. 133-135).—Bordeaux mixture having failed to control citrus canker on badly infected nursery stock of *C. mitis*, *C. nobilis*, and *C. aurantium* in 1915, tests were made with 1 part 38 per cent formaldehyde in 120 parts of water and later with a 1:100 solution applied to the plants and soil, combined with the removal of the infected leaves and severe pruning. The disease was checked and a healthy growth resulted, subsequent outbreaks of the disease being attributed to the release of infecting material by the turning of the soil. The outbreaks were readily controlled by the use of the same treatment, no new infections being apparent at the time of the report.

Further tests with formalin sprays are being made at both the Singalong and the Lamao stations.

Notes on the citrus canker, P. J. WESTER (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 2, pp. 155-157).—It is stated that the author first saw citrus canker in the Philippines in 1912 at the Lamao Station, but that he then considered it a virulent form of scab. Though present ever since that time, it caused no serious trouble until after the rainy season of 1914. An account is given of the localities in which it has been noted. What is thought to be citrus canker has been discovered on 22 species or varieties of Citrus in the Philippines as here listed. *C. nobilis*, *C. nobilis papillaris*, *C. mitis*, and *C. webberii montana* appear to be practically immune, *C. aurantium* and *C. decumana* very variable, and a few named are particularly susceptible to citrus canker. The disease is generally most destructive when the plants are less than a meter in height.

In 1915, the disease was noted in eastern and western Java and in Singapore. This fact, its occurrence in the Philippines on some of the most primitive Citrus forms, as well as on the native taboc, and its prevalence in China and Japan suggest that the citrus canker may be widespread in Malaysia and perhaps in Indian and Ceylon.

Diseases of the lime tree, J. B. HARRISON, O. K. BANCROFT, and G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 9 (1916), No. 3, pp. 122-126).—In this report, which deals also with insect pests of limes, mention is made of leaf yellowing, ascribed to soil conditions; staghead, due to constant winds; citrus knot, usually associated here with *Loranthus theobromæ*; gummosis, connected with adverse soil conditions; withertip, leaf spot, or anthracnose, caused by *Colletotrichum glæosporioides*; sooty mold, consisting of the nonparasitic but injurious *Capnodium citricolum*; a root invasion by *Fomes semitostus*; a brown root disease, caused by *Hymenochæte nozia*; lichens on trunks and leaves; and bird vine (*L. theobromæ*).

A Phoma disease of lavender, W. B. BRIERLEY (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, No. 5 (1916), pp. 113-131, pls. 2, figs. 9).—A serious disease of *Lavandula*, apparently confined to this genus, is due to *P. lavandulæ*, which is here, supposedly for the first time, recorded for England, with an account of a study made by the author on the characters and habits of the causal organism. The mycellum ramifies throughout the tissues of the host, causing collapse of the cortex and pith groups, the hyphæ passing from cell to cell through the abundant pits in the cell walls. The pycnidia form below the epidermis which is thus lifted from the cortex. Chlamydo-spores are occasionally formed, but conidia have not been known to occur in the normal life cycle.

The extension of *Marsonia rosæ* on rose bushes, J. CHIFFLOT (*Assoc. Franc. Avanc. Sci., Compt. Rend.*, 43 (1914), pp. 426-428).—It is stated that *M. rosæ*, formerly confining its attacks to the foliage, may, in case of certain varieties, extend itself to all the aerial portions of the plant.

*Roesleria pallida*, JESSIE S. BAYLISS-ELLIOTT and W. B. GROVE (*Ann. Bot. [London]*, 30 (1916), No. 119, pp. 407-414, figs. 11).—The authors have made a study of a fungus growing on the roots of a willow which had died at the end of the autumn, 1915, after passing through a period of gradual exhaustion. The fungus supposed to be the cause of the trouble and at first thought to be *Pilacre petersii* was carefully studied in connection with others supposedly related thereto.

It is stated that the fungus in question proved to be *R. pallida*, which is described, as existing descriptions are considered to require important modifications. It is thought that *Pilacre* is probably a conidial stage of species of *Roesleria* (*R. pilacrisformis* being only a slender form of *R. pallida* and *P. petersii* being identical with *P. faginea*). These species of *Pilacre* are con-

idiophorous, not basidiphorous, and are not connected with the Auriculariæ or the Tremellinæ.

[*Hevea dieback in Sumatra*], J. G. C. VRIENS (*Meded. Adv. Alg. Ver. Rubberplanters Oostkust Sumatra, No. 2 (1915), pp. 19-21; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1706, 1707*).—The serious diseases of *Hevea* in Sumatra are said to be those due to *Fomes semitostus*, *Phytophthora faberi*, *Corticium salmonicolor*, *Hymenochaete noxia*, and *Thyridaria tarda (Botryodiplodia theobromæ)*. The last named fungus is the cause of a dieback which is described. The trees may recover if the weather is dry and favorable, but attack on the trunk is liable to be followed by the death of the tree and the spread of the disease to neighboring trees. The disease is said to be controllable by spreading tar on the infected spots and, as soon as this is dry, cutting out and burning the tarred spots.

### ECONOMIC ZOOLOGY—ENTOMOLOGY.

**A history of British mammals**, G. E. H. BARRETT-HAMILTON and M. A. C. HINTON (*London: Gurney & Jackson, 1916, vol. 2, pt. 19, pp. 601-648, pls. 2, figs. 4*).—This continuation of the Muridæ (E. S. R., 35, p. 656) deals with the genus *Epimys*, including the tree or roof rat (*E. rattus frugivorus*) and the brown or common rat (*E. norvegicus*); and the genus *Mus*, including the house mouse (*M. musculus*).

**Gopher destruction**, J. H. GRISDALE (*Canada Expt. Farms Bul. 31, 2. ser. (1916), pp. 8, figs. 4*).—This describes methods of combating gophers, which are among the worst enemies of the farmer on the prairies in the Provinces of Manitoba, Saskatchewan, and Alberta.

**The control of voles in Italy**, A. SPLENDRE (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), II, Nos. 1, pp. 46-49; 6, pp. 218-224; 12, pp. 516-521; abs. in Nature [London], 98 (1916), No. 2461, p. 338*).—This is a report of work carried out at the entomological laboratory of the University of Rome with a view to finding some satisfactory method of controlling voles (*Pitymys savi*), an outbreak of which in the Province of Foggia in Apulia during the summer resulted in an almost entire destruction of the grain crop.

A spontaneous outbreak of a disease among voles sent the author for study resulted in the death of a number en route, while the remainder died a few days after their arrival in Rome. In all of these voles a coccobacillus was present in the blood, the internal organs, and the lymphatic glands. There was a remarkably high mortality among voles in the vicinity of Cerignola. The epizootic, which spread extensively, presented the features of a septicemia, the internal organs being congested, especially the spleen and liver, which were always enlarged. A comparison of the coccobacillus with *Bacillus typhi murium* and the typhi-coli group shows it to represent a new species which he describes as *Bacterium pitymysi*.

Voies obtained from a locality where the epizootic was not known to occur died in less than 24 hours after subcutaneous inoculation with an emulsion of the spleen or liver of an infected vole, while others fed with infected material died in three or four days. When dead or infected voies were placed among healthy ones, the latter developed the disease in a few days, and it was also pathogenic for mice, rats, and rabbits.

The organism was isolated from the intestine of fleas found on an infected vole, and the injection into a healthy vole of the intestinal contents of three such fleas resulted in its death in less than 24 hours. Another healthy vole placed in a vessel with three vole fleas died three days later. Both voies were

found to exhibit the usual congestion of the internal organs and to contain the coccobacillus. The author considers the experiments to confirm his previous suspicion that the fleas serve as the natural method of transmission. He recommends that voles infected by inoculation be distributed in the areas invaded by voles, where the epizootic has not yet appeared, so that the disease will be propagated by fleas and continually extend until the areas are freed from the rodents.

**Destruction of oysters by crabs, J. NELSON** (*New Jersey Stas. Rpt. 1915, pp. 249-251*).—Observations have led to the conclusion that crabs are a source of destruction of oysters, though it is possible that some other enemy destroys the oyster and that the crab cleans out the dead meat. Observations extending over many months have failed to show that living water fleas, snail larvæ, worm larvæ, etc., swallow oyster fry. One very abundant copepod, thought to be a species of *Calanus*, is, however, suspected of feeding on oyster fry.

**Insect enemies, C. A. EALAND** (*London: Grant Richards Ltd., 1916, pp. XIII+223, pls. 23*).—In this work the author enumerates the life histories and destructive habits of a number of important British injurious insects, and gives descriptions enabling them to be recognized and methods by means of which they may be held in check.

**Mushroom pests and how to control them, C. H. POPENOE** (*U. S. Dept. Agr., Farmers' Bul. 789 (1917), pp. 13, figs. 7*).—A revision of Bureau of Entomology Circular 155, previously noted (*E. S. R., 27, p. 657*).

**Pests of sugar cane in British Guiana, J. C. HUTSON** (*Agr. News [Barbados], 15 (1916), Nos. 382, pp. 410, 411; 383, pp. 426, 427*).—This is a review of the reports by H. W. B. Moore on the insect pests for the years 1914 and 1915, which relate entirely to the enemies of sugar cane in British Guiana and their control.

**General report on insect pests for the year 1915, H. W. B. MOORE** (*Demerara, Brit. Guiana: The Argosy Co., Ltd. [1916], pp. 8*).—Noted above.

**Some new or little-known enemies of fruit trees, N. A. KEMNER** (*Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 133 (1916), pp. 21, figs. 12; K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 5, pp. 413-429, figs. 12; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 8, p. 354*).—This paper deals particularly with the shot hole borer, *Magdalis pruni (ruficornis)* which occurs in company with the shot hole borer, and *Anobium rufipes*, which is attacked by a braconid (*Hecabolus sulcatus*). A key to the insects attacking the branches and trunks of fruit trees, according to the nature of the injury, is appended to the paper, as is a list of 37 references to the literature.

**Insects injurious to pine and fir trees in Sweden, I. TRÄGÅRDH** (*Skogsvårdsför. Tidskr., 13 (1915), No. 11, pp. 813-874, figs. 49; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 3, pp. 464, 465*).—An account of the Microlepidoptera injurious to pine and fir trees in Sweden, with a list of references to the literature.

**Measures for avoidance and extermination of flies, mosquitoes, lice, and other vermin, H. MAXWELL-LEFROY** (*Calcutta and Simla: Thacker, Spink & Co., 1916, 2. ed., pp. 17, figs. 5*).—This second edition of the paper first issued in 1915 gives simple instructions for avoiding the attacks of disease-carrying insects and for their extermination. It includes new methods devised during the latter half of 1915 and used by the army in France and the Mediterranean region, together with information especially applicable to India.

**Twenty-ninth report of the state entomologist on the noxious and beneficial insects of the State of Illinois, S. A. FORBES** (*Rpt. State Ent. Ill., 29 (1916), pp. IX+127, pl. 1, figs. 24*).—This report consists of a number of papers all of which, with the exception of one, On the Life History of the Codling

Moth, by S. A. Forbes and P. A. Glenn (pp. 1-21), are by the author and have been previously noted, namely, A General Survey of the Maybeetles (*Phyllophaga*) of Illinois (pp. 23-65) (E. S. R., 35, p. 158); The Influence of Trees and Crops on Injury by White Grubs (pp. 66-70) (E. S. R., 35, p. 159); and The Chinch Bug Outbreak of 1910 to 1915 (pp. 71-127) (E. S. R., 36, p. 153).

The paper relating to the codling moth gives the main practical results of work in 1915 in addition to the information given in the paper previously noted (E. S. R., 34, p. 251). The data obtained concerning both insects and weather have been brought together in two diagrams. There were found to be two complete generations of the codling moth in both central and southern Illinois during 1915, and a small or partial third generation at Olney and farther south.

It is found that the temperature of the season has very much to do with the rate at which the successive changes go on, the time at which the different generations make their appearance, reach their largest numbers and disappear, and with the size and importance of the last or third generation of the year. It is pointed out that 1914, when a total failure to control the pest resulted in some orchards notwithstanding the fact that sprays had been applied six, and in some cases seven times, was a very different year from 1915 throughout southern Illinois, not only in respect to temperature and other weather conditions but also in the number and importance of the last generation of the codling moth.

The authors are convinced that the successful timing of spraying operations to the life history of the insect so that effective poisons may be on the apples when they are most needed and will be most destructive to the young apple worms requires a careful and intelligent observation of the course of events for each year. They believe that for the best results a well-equipped observation station with an experienced man in charge is necessary for each of the principal fruit sections of the State, but propose a practical method by which the fruit grower can himself follow the course of events through the season in a way to serve fairly well the necessities of the case, enabling him to learn for himself and for the fruit growers in his region about when spraying should be done and how often repeated to protect his crop.

**Entomological report for 1915, E. N. CORY** (*Rpt. Md. State Hort. Soc., 18 (1915), pp. 151-163*).—This reports briefly upon the occurrence of the more important insects in Maryland during 1915.

**Report of the department of entomology, T. J. HEADLEE** (*New Jersey Stat. Rpt. 1915, pp. 297-335*).—The several parts of this report include a tabular statement of the insects and other animals about which correspondents have written; the occurrence of the more important insects of the year, including the tent caterpillar, apple and other plant lice, pear psylla, white grub, the rose-chaffer, flea-beetles, army worm, Angoumois grain moth, the European pine shoot moth (*Evetria buoliana*), the European mole cricket (*Gryllotalpa gryllotalpa*), etc.; and investigations.

Control work was carried on with the mushroom spring-tail (*Achoreutes armatum*), which was a source of injury at Irvington. Carbon bisulphid was found to destroy the spring-tails, but its use resulted in such serious injury to the mushrooms that it can not be considered as a remedy. In control work with white grubs it appears that the minimum dose of carbon bisulphid on red shale soil is not far from 0.75 oz. to the square foot. Even when used much stronger up to November 1 there was no trace of injury to either blue grass or clover on any of the plats, indicating that the minimum dosage for the grub is well below the maximum dosage for blue grass and white clover. In the control of the rose-chaffer on apple self-boiled lime-sulphur plus lead arsenate was the

most effective, giving almost perfect protection. Since no dead beetles were found under the trees treated with self-boiled lime-sulphur it seems probable that the mixture acted purely as a repellent and that lead arsenate had little or nothing to do with the result. In experiments with the potato flea-beetle a mixture consisting of 1 lb. of pyrethrum, 10 gal. of water, and 10 oz. whale-oil soap was effective, but its cost was practically prohibitive. Plants given four treatments with home-mixed Bordeaux (5:5:50) showed 50 per cent reduction in the beetles' work.

In observations of the hibernation of the strawberry weevil this pest was found in woodlands adjacent to strawberry patches in abundance on moss stems (*Dicranum scoparium*) about 0.25 in. below the summits. As recorded in a circular previously noted (E. S. R., 35, p. 364), a mixture of powdered arsenate of lead and sulphur gave better protection than any of the other substances tried, and a mixture composed of one part of the lead to one part of sulphur was a little the more effective. It appears, however, that it is neither the arsenate of lead alone nor the sulphur by itself which is effective, but the mixture of the two.

In the work with the peach borer neither the Scott protectors nor the asphalt coatings gave satisfactory results, due to incompleteness of the covering. In investigation of the effect of moisture upon lethal high temperature the bean weevil (*Bruchus obtectus*) was experimented with, and a few tests made with the pea weevil (*B. pisorum*). It was found that a difference of from 92 to 94 per cent relative humidity has practically no effect upon the lethal temperature for the unprotected bean weevil. Large increases in relative humidity, as from 94 to 96 per cent, have less influence on the lethal temperature than has a change of 5° F.

The report concludes with a discussion of potato dusting and spraying experiments in continuation of those of the previous year (E. S. R., 34, p. 158). In the work with the regular crop there was found to be very little difference between the cost of dusting and spraying, except when an arsenical was used by itself. While the returns from sulphur zinc and sulphur lead were not as large as those from home-mixed Bordeaux, they are considered to have been good. In the work with the second crop the differences between yields from zinc sulphur and lead sulphur on the one hand and lead arsenate alone on the other in the control of the Colorado potato beetle were easily within the limits of experimental error.

[Entomological investigations] (*New Jersey Stat. Bul.* 298 (1916), pp. 33-38).—This is a brief report of investigations on the influence of atmospheric moisture upon insect metabolism; methods of controlling the strawberry weevil, apple aphid, false cabbage aphid, and pear psylla; the efficiency of certain types of covers for wintering bees; the food preference of the common house fly; and the problems connected with mosquito control.

Thirty-first report of the state entomologist on injurious and other insects of the State of New York, 1915, E. P. FELT (*N. Y. State Mus. Bul.* 186 (1916), pp. 215, pls. 18, figs. 39).—A brief statement of the occurrence of the more important injurious insects, the work of the office, etc., is followed by a report of observations and work with the more important pests.

Work with the codling moth (E. S. R., 33, p. 252), was continued, spraying experiments in Albion, Monroe, and Niagara counties being reported upon at length, together with observations of the leaf roller made during these experiments. Much of the data is presented in tabular form. A general survey of conditions in the apple belt in the western part of the State has shown that some growers are able to obtain practically worm-free apples by one spraying for

the codling moth, others with two or three applications, while many suffer great losses in spite of frequent and apparently thorough treatments. It is pointed out that the first spraying made just after blossoming is by far the most effective application. It is thought that the second spray will be most effective in reducing side injury if made the latter part of June, but so far as checking the pest is concerned it does not seem to be essential. "Both the second and third sprayings for the codling moth, even if they have comparatively little influence in reducing the numbers of this pest, are abundantly justified in localities where scab is more or less prevalent, assuming, of course, that a fungicide is universally added to the poisoned spray."

Other important species considered are the chrysanthemum midge (*Diarthronomyia hypogaea*), which was a source of injury at Adrian, Mich., etc.; white grubs, a serious outbreak of which occurred in southern Rensselaer and northern Columbia counties; grasshoppers, investigations of which were continued in Fulton and Saratoga counties; and mosquitoes, the control of which was undertaken in cooperation with the Sodus Bay Improvement Association. A report of biological observations of various mosquitoes by the author and H. H. Stage follows, and an account is then given of oil injuries to the bark of deciduous trees resulting from the use of an oil compound in combating the hickory bark beetle, lined chestnut borer, etc. In an experimental test of an oily preparation, widely recommended under a trade name, upon various forest trees with diameters of 1 to 2 in., six out of ten trees died within six months and the others showed signs of serious injury.

Under the heading of Notes for the Year, fruit tree insects mentioned include the apple maggot, which is becoming abundant in some fruit-growing sections in the Hudson Valley; the red bug (*Heterocordylus malinus*) and the lined red bug (*Lygidea mendax*), both of which are widely distributed in the Hudson Valley, practical work in the control of which during the summer demonstrated the efficacy of a tobacco extract application just before the blossoms open; the San José scale, which was less abundant in the Hudson Valley, due to natural agents, including small parasites; the sinuate pear tree borer, which is extending its range from New Jersey into New York State; the pear thrips, the depredations of which were especially severe in the Hudson Valley owing to weather conditions favorable to its activities; the pear psylla; the quince curculio; and the cherry leaf beetle (*Galerucella cavicollis*), which appeared in large numbers in widely scattered localities and fed upon cherry and peach tree foliage, but without serious damage to the trees. Forest tree insects mentioned are the white-pine weevil (*Pissodes strobi*); ugly nest cherry worm (*Archips cerasivorana*); another pine twig borer *Dioryctria abietella*, which was found working in the buds of Austrian pine at Rochester; the periodical cicada, a scattering infestation of which was reported in the Hudson Valley; and the recently established bayonet or post-horn pine borer which bids fair to become a serious enemy of the native pines. The grass webworm (*Crambus luteolellus*), the lined spittle insect (*Philænus lineatus*), and the European spittle insect (*P. spumarius*) were injurious to grasses.

Lists of the publications of the entomologist and of the more important additions to collections, October 16, 1914 to October 15, 1915, are also given. Part 4 of A Study of Gall Midges (E. S. R., 34, p. 752), which deals with the tribe Asphondyliariæ, is appended.

[Report of entomological investigations] (*Wisconsin Sta. Bul. 275 (1917)*, pp. 46-49, figs. 5).—In work with the codling moth on apple, excellent control was secured from the use of powdered arsenate of lead at the rate of 1.5 lbs. to 50 gal. of spray in four applications known as the "pink," "calyx," "second moth," and "summer" sprays. Brief reference is made to improved methods of

rearing queen bees, the results of two seasons' work showing that successful queen production is practically assured. Studies were made of the banded apple aphid, commonly known as the grain or oat aphid, which is the common plant louse on apples in Wisconsin. Experiments in several orchards have shown that it is impossible to control this pest through the use of blackleaf 40 at a strength of 1 to 3,000.

Notes on early stages and life history of the earwig (*Forficula auricularia*), T. A. CHAPMAN (*Ent. Rec. and Jour. Variation*, 29 (1917), No. 2, pp. 25-30, pls. 3).—This paper presents observations on the biology of this earwig.

Combating *Schistocerca peregrina* in Morocco in 1916 by the biological method, H. VELU (*Bul. Soc. Path. Exot.*, 9 (1916), No. 9, pp. 682-684).—A report of work carried on in continuation of that previously noted (*E. S. R.*, 36, p. 755).

*Calocoris angustatus*, E. BALLARD (*Agr. Research Inst. Pusa Bul. 58* (1916), pp. 8, pl. 1, fig. 1).—An account of the life history and of control measures for this capsid, which is a serious enemy of *Andropogon sorghum* all over southern India.

The rose leaf hopper (*Typhlocyba rosæ*) and a new egg parasite of it, A. TULLGREN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 132 (1916), pp. 13, figs. 7; *K. Landtbr. Akad. Handl. och Tidskr.*, 55 (1916), No. 5, pp. 404-412, figs. 7; *abs. in Rev. Appl. Ent.*, Ser. A, 4 (1916), No. 8, p. 353).—*T. rosæ*, a well-known pest of roses, is widely distributed in Sweden, occurring wherever its native food plant, the wild briar, is found. The eggs are parasitized by a mymarid (*Anagrus bartheli*), here described as new.

Solubility of the scale of *Lepidosaphes ulmi*, S. MAULIK (*Bul. Ent. Research*, 7 (1917), No. 3, pp. 267-269, fig. 1).—The author concludes that the scale of this coccid is probably not a wax and that the ingredients of the spraying fluids in use have no solvent action on the scale. Thus any good results obtained with these fluids depend on the physical properties of the paraffin oil contained in them. "Scrubbing the trunks with a hard brush and hot water in winter, and then spraying with weak kerosene emulsion in the following spring only those trees which show newly-hatched insects on them are better methods of checking the spread of the oyster-shell scale."

Simon's hot-air machine for the treatment of cotton seed against pink bollworm, G. STOREY (*Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 11* (1916), pp. 7; *abs. in Rev. Appl. Ent.*, Ser. A, 4 (1916), No. 12, p. 491).—A description is given of a machine of the type used in England for drying malt, which was tested to determine its suitability for treatment of cotton seed infested by the pink bollworm. The optimum temperature for this machine seems to lie between 131 and 133° F., but at all temperatures tested a small percentage of the larvæ survived and a small percentage of the seed was damaged. It is concluded, however, that the machine will fulfill all practical requirements. The details of the experiment are reported in tables.

Peach borer observations at Vineland, M. A. BLAKE and C. H. CONNORS (*New Jersey Stat. Rpt. 1915*, pp. 48-51, pl. 1).—The observations here reported are based upon records kept of the number of borers removed annually from each tree in the experimental orchard at Vineland, in continuation of observations of 1913 and 1914 previously noted (*E. S. R.*, 34, p. 161).

The authors' observations refute the quite general belief that the borer works in the roots at no great depth from the surface of the ground, since many small borers were found in the large side roots many inches below the surface in a tree dug up which contained 72 borers. Thus it appears to be extremely doubtful if more than a small proportion of the borers in badly infested trees

are destroyed by examination of the trunk to a depth of from 8 to 10 in. A diagram gives the plans of three orchards and indicates the number of borers removed from each tree during 1915.

It appears that there has been an increase each year in the number of borers found in the trees in spite of thorough work in borer removal. Records kept of the 675 trees of orchard No. 1 show that in 1913 about one-half of the trees contained borers, whereas in 1915 nearly 75 per cent contained borers. In orchard No. 2 there was a decrease in both the number of trees infested and in the total infestation, while in orchard No. 3 there was an increase from 1913 to 1915 of over 63 per cent in the number of trees infested and an increase of more than 125 per cent in the number of borers removed.

A codling moth trap, E. H. SIEGLER (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 517-521, pl. 1).—Failure to control the codling moth in the Grand Valley of Colorado, notwithstanding the fact that from five to eight thorough spray applications were made, led to the use of the trap here described, which consists of a strip of wire screen cloth 6 in. in width and sufficiently long to encircle the trunk of the tree. It is based upon the knowledge that the codling moth larva will enter an opening through which, after its transformation, the adult can not escape. In preliminary experiments reported 41 per cent of the larvæ cocooned within the traps.

The effect of cold upon malaria parasites in the mosquito host, W. V. KING (*Jour. Expt. Med.*, 25 (1917), No. 3, pp. 495-498, pls. 2).—In continuation of investigations of malarial parasites in the mosquito (*E. S. R.*, 35, p. 360) the author reports upon work conducted at New Orleans from September to December, 1916.

The experiments here reported show that the parasite of tertian malaria in the mosquito host is able to survive exposure to a temperature of 30° F. for a period of two days, or 31° for four days, and a mean temperature of 46° for 17 days. In a smaller series of tests the sporonts of the estivo-autumnal parasite have shown a resistance to temperatures as low as 35° for 24 hours.

Report on mosquito work for 1915, T. J. HEADLEE (*New Jersey Stat. Rpt. 1915*, pp. 339-364).—A detailed report of the work of the year in the control of salt marsh mosquitoes, assistance rendered boards of health and county commissions in mosquito extermination, etc., and brief observations on the mosquitoes of the year.

On the biology of two tachinids which have an intramuscular stage (*Plagia trepida* and *Sturmia scutellata*), W. R. THOMPSON (*Compt. Rend. Soc. Biol. [Paris]*, 78 (1915), No. 3, pp. 717-721, figs. 5; *abs. in Jour. Roy. Micros. Soc.*, No. 4 (1916), p. 377).—The eggs of *Plagia* containing larvæ ready to hatch out are deposited on the body of the host. Upon emerging, the larva traverses the skin and after entering the general cavity passes into a muscle where it remains to the end of the primary stage. It then forms a secondary tegumentary air hole in connection with which it passes the second and third stages, but leaves the host before pupation.

The eggs of *Sturmia* are deposited on leaves which form the food of the host. Upon being devoured by a caterpillar they hatch in the alimentary canal and the larvæ pass out into the general cavity and thence into a muscle.

*Sarcophaga froggatti*, n. sp.—A new sheep maggot fly, F. H. TAYLOR (*Bul. Ent. Research*, 7 (1917), No. 3, p. 265).—Under the name *S. froggatti* the author describes a new sarcophagid found to attack sheep at Winton, Queensland.

On the life history and structure of *Telephorus lituratus*, OLGA G. M. PAYNE (*Jour. Zool. Research*, 1 (1916), No. 1, pp. 4-32, pls. 2, figs. 18; *abs. in Rev. Appl. Ent.*, Ser. A, 4 (1916), No. 8, pp. 321, 322).—This is a report of studies

at Manchester, England, of the malacoderm beetle *T. lituratus*. The larvæ were found among and below the roots of grass at a depth of about 2 in., but were more abundant near the roots of trees, especially elder and rhododendron. It appears that the larvæ are primarily carnivorous, but whether they are beneficial is doubtful.

Notes on the twelve-spotted cucumber beetle, R. A. SELL (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 551-556).—These notes relate to the biology of *Diabrotica duodecim-punctata*, which is becoming more numerous in southern Texas.

The rose flea-beetle (*Haltica probata*), G. F. MOZNETTE (*Jour. Ent. and Zool.*, 9 (1917), No. 1, pp. 13-19, figs. 7).—A brief account is given of the seasonal life history and habits of *H. probata*, to which, in a review of the literature, the author has failed to find more than a brief reference. This species has been reported from Spokane, Wash., and Nelson, B. C., attacking the strawberry, and at various times has been reported as feeding on cultivated crops in Oregon. It is distributed along the Pacific coast from British Columbia to California, and there appears to be some possibility of its becoming destructive to cultivated roses.

Observations on its life history and habits are given, together with technical descriptions of its several stages.

Otiiorhynchus sulcatus, an enemy of pot plants, N. A. KEMNER (*Trädgården [Stockholm]*, No. 18 (1916), p. 145, figs. 2; *abs. in Rev. Appl. Ent.*, Ser. A, 4 (1916), No. 8, pp. 354, 355).—The larvæ of this weevil are often introduced into pots with soil from infested greenhouses, and instances are known where as many as 20 larvæ have been found in one pot. The adults damage the leaves of various plants, especially ferns, rhododendrons, orchids, etc. The injury to the roots by the larvæ, though much more serious, is often overlooked.

The leaf weevil (*Polydrusus impressifrons*) in New York, P. J. PARROTT and H. GLASGOW (*Ann. Rpt. Ent. Soc. Ontario*, 46 (1915), pp. 60-65).—The leaf weevil, preliminary studies of which are reported, is a new and, until the inception of this study, an unrecorded enemy of shade and fruit trees in this country, brief reference to which has been previously noted (E. S. R., 29 p. 252). Its range in New York State has not been definitely established, but it is known to have become established in Ontario, Monroe, and Wayne counties, and to occur in scattering numbers as far west as Albion, in Orleans County. The damage which it causes is due to nibbling the unfolding buds and then attacking the foliage, preferring the margins of the leaves. Where sufficiently abundant to warrant their use, it is thought that arsenicals will control it.

Notes on the control of the white pine weevil, S. A. GRAHAM (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 549-551).—During the season of 1916 the author applied different materials at various strengths to young pine trees in an effort to control *Pissodes strobi*. Of the materials used, none but creosote and carbolineum proved effective. The results seem to warrant a further trial of these two materials and also Tanglefoot, which was applied to 40 trees, on a larger scale.

An Indian ant introduced into the United States, W. M. WHEELER (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 566-569, fig. 1).—This paper records the collection of *Triglyphothrix striatidens* at Audubon Park, La., in August, 1913, and gives a description and drawing of it and a review of its literature.

Two new genera of North American Entedoninæ (chalcid flies), A. A. GIRAULT (*Canad. Ent.*, 49 (1917), No. 3, pp. 110, 111).—The genera *Elachertomyia* and *Emersonopsis* are erected.

The privet mite in the South, E. A. MCGREGOR (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 556-561, pl. 1, fig. 1).—This paper relates to *Tenuipalpus bioculatus*

which appears to be confined to seven southeastern States from North Carolina to Louisiana, inclusive. Tests of insecticides showed that both lime-sulphur and potassium sulphid caused a mortality of 99 per cent, whereas nicotin sulphate destroyed less than 5 per cent.

Contribution to the knowledge of the life history and habits of *Tychius 5-punctatus*, G. GRANDI (*Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici*, 10 (1915), pp. 103-119, figs. 6).—Injury caused by this weevil to beans in the commune of Ruvo di Puglia, Italy, led to the studies here reported.

### FOODS—HUMAN NUTRITION.

Digestibility of some vegetable fats, C. F. LANGWORTHY and A. D. HOLMES (*U. S. Dept. Agr. Bul. 505* (1917), pp. 20).—Employing the same methods as those used in earlier work in the study of the digestibility of animal fats (*E. S. R.*, 34, p. 364), the authors report the results of a study of the digestibility of vegetable fats, viz, cottonseed, peanut, coconut, and sesame oils, and coco butter. These fats were incorporated in blancmange or cornstarch pudding, which was given with a basal ration of wheat biscuits, oranges, sugar, and tea or coffee. Normal young men served as subjects of the experiments. The following quotations are from the authors' conclusions:

"With allowance for metabolic products, the coefficients of digestibility have been found to be for olive oil, 97.8; for cottonseed oil, 97.8; for peanut oil, 98.3; for coconut oil, 97.9; for sesame oil, 98; for cocoa butter, 94.9 per cent. These values indicate that the vegetable fats studied, with the exception of cocoa butter, have for all practical purposes the same digestibility and are utilized as completely as the animal fats.

"The melting points of these fats are considerably lower than body temperature (37° C.), and in accordance with the theory that fats of low-melting points are more thoroughly digested than the harder fats, it has been found that the vegetable fats studied, with the exception of cocoa butter, are utilized practically completely by the body.

"The average amounts of fat eaten per subject daily were 73 gm. of olive, 86 gm. of cottonseed, 98 gm. of peanut, 64 gm. of coconut, and 90 gm. of sesame oils. Moreover, as much as 103, 125, 113, 131, and 106 gm. of these fats, respectively, were eaten by one of the subjects for a 3-day period without any physiological disturbance. In the first eight experiments with cocoa butter, in which an average of only 51 gm. of this fat was eaten daily, no abnormal conditions were noted and the apparent digestibility of fat was 90.7 per cent. In those experiments, however, in which from 82 to 138 gm. of cocoa butter were consumed daily and 86.5 per cent utilized, a decided laxative effect was noted. Accordingly it may be concluded that the limit of tolerance is less for cocoa butter than for the other fats studied.

"The evidence collected in these experiments affords additional proof that the digestibility of protein and carbohydrate contained in the different fat diets was not materially affected by the nature of the fat or by the amount eaten. . . .

"Judging from the results of the investigation as a whole, it is reasonable to conclude that olive, cottonseed, peanut, coconut, and sesame oils are very completely and readily available to the body and that they may, like the animal fats, be satisfactorily used for food purposes."

Studies on the digestibility of some animal fats, C. F. LANGWORTHY and A. D. HOLMES (*U. S. Dept. Agr. Bul. 507* (1917), pp. 20).—This bulletin reports data regarding the digestibility of chicken, goose, beef-brisket, egg-yolk, and fish fats, as well as cream. The experiments are in continuation of earlier work (*E. S. R.*, 34, p. 364). As in the above experiments, normal young men

served as subjects and the fats studied were incorporated in a basal ration. The results of the investigation are summarized in part as follows:

"The fats studied in this investigation were well digested, the coefficients of digestibility, with allowance for metabolic products and any undigested fat supplied by the basal ration, being, for chicken fat, 96.7 per cent; for goose fat, 95.2 per cent; for brisket fat, 97.4 per cent; for butter fat in the form of cream, 96.9 per cent; for the fat in egg yolk, 93.8 per cent; and for the fat in fish flesh, 95.2 per cent.

"On an average, 95 gm. of chicken fat, 95 gm. of goose fat, 80 gm. of brisket fat, 78 gm. of butter fat in the form of cream, 83 gm. of egg-yolk fat, and 60 gm. of fish fat were eaten per subject per day. In the case of goose fat, the feces were noticeably soft and occasionally a more decided laxative effect was noted, indicating that the limit of tolerance for this fat was not far about the 95 gm. which was eaten on an average. No physiological disturbance was noted with the other fats tested. Such matters have a practical value in discussing dietetics, aside from the theoretical question whether this laxative property is ascribable to differences in the chemical structure of the fats or to some other factor.

"The average coefficient of digestibility of brisket fat is higher than that previously found for beef (kidney) fat (93 per cent), which is in accordance with the observation that the digestibility is inversely proportional to the melting point. The other fats studied were either fluid or had a melting point not far from room temperature, so it was not surprising to find that they did not show marked variations in thoroughness of digestion."

**The solidity of oysters, J. NELSON** (*New Jersey Stas. Rpt. 1915, pp. 242-246*).—The solidity of oysters is defined as the proportion of the contents of an oyster shell that is nutrient, as distinct from the water present. This is discussed in connection with the practice of floating oysters before sale, especially with reference to the question of standards for determining the amount of such adulteration. It is stated that three distinct practices in connection with the swelling of oysters from the use of water fresher than that in which they are grown must be considered. These are, first, the practice of floating oysters in the shell; second, the practice of washing shucked oysters that are marketed as solid meat without liquor; and third, the practice of retailers to put the open oysters into a bucket of tap water, from which they are sold after standing for a varying length of time. The results are reported of analyses of several samples of oysters for solidity, and it is stated that each of the three cases mentioned above must be studied on its own merits, and that the problem of standards in any of these cases is much more complicated than in the case of milk adulteration.

The author states that there is need of further investigation of the rate and amount of swelling in each of these cases, and also of the injuries and benefits connected with various methods of handling oysters for sale. From the standpoint of health the real menace in the practice of floating oysters lies in the possibility of infection through the use of contaminated water.

**Copper content of green oysters, J. NELSON** (*New Jersey Stas. Rpt. 1915, pp. 242-249*).—This article contains a rather extended discussion of the copper content of oysters and the green color sometimes observed in these shellfish in certain localities. It is pointed out that various samples of shellfish, which are alike in showing the green color, are unlike in respect to the amount of copper present. The metal may be absent from the colored substance in some cases and some samples of uncolored shellfish may contain more of the metal than others which are colored. There is, therefore, no reason to believe that the green color is due to copper. It is further pointed out that copper is present

in the blood and tissues of shellfish, where it probably plays some part in respiration in the same way that iron does in the red-blooded animals.

Determinations were made of copper in several samples of oysters which showed marked blue coloration. Using the color test with potassium ferrocyanid, the three blue samples were found to contain about 40 mg. of copper apiece and the uncolored ones 9 mg. Using the more reliable method for determining copper by electrolysis, less than half of this amount of copper was obtained.

General statistics of the [Alaska] fisheries in 1915, W. T. BOWER and H. D. ALLER (*U. S. Dept. Com., Bur. Fisheries Doc. 834 (1917), pp. 28-68*).—A compilation of statistical data regarding the canning, curing, pickling, freezing, dry salting, drying, and smoking of salmon. Data are also included regarding the halibut, cod, herring, and whale fisheries, as well as the minor fisheries (trout, black cod, shellfish, etc.).

Some new constituents of milk.—II, The distribution of phosphatids in milk, T. B. OSBORNE and A. J. WAKEMAN (*Jour. Biol. Chem., 28 (1916), No. 1, pp. 1-9*).—The experiments here reported were carried out to extend earlier work (*E. S. R., 33, p. 660*). The following conclusions are drawn:

"Alcohol removes from milk casein, precipitated by dilute hydrochloric acid, about the same amount of phosphatids as was previously obtained from the 'lactalbumin' obtained by heating the filtrate from the casein. Since the amount of casein is more than six times as much as the 'lactalbumin,' the proportion of phosphatid which it yields is correspondingly less.

"The precipitate produced by treating skimmed milk, freed from casein and heat-coagulable proteins, with sodium hydroxid until neutral to phenolphthalein contains a very small amount of the same phosphatids and fatty substances that can be obtained from the alcoholic washings of the heat-coagulable proteins ('lactalbumin'). The nonprotein fractions of fat-free milk contain at the most only minute traces of phosphatids. The total amount of phosphatids obtained from 1 liter of whole milk was equal to about 27 mg.

"Phosphatids are intimately associated with the protein constituents of milk and possibly are combined with them as 'lecithalbumins.'"

Milk: A cheap food, FLORA ROSE (*Cornell Reading Course for Farm Home, No. 3 (1917), pp. 73-85*).—This bulletin discusses the cost of milk as a source of body-building materials and body-regulating substances. It includes an outline for study clubs on the food value of milk and a bibliography of references on its nutritive value.

The colloidal swelling of wheat gluten in relation to milling and baking, F. W. UPSON and J. W. CALVIN (*Nebraska Sta. Research Bul. 8 (1916), pp. 27, figs. 5*).—The experiments reported in this bulletin deal with the changes in hydration capacity of gluten under different conditions, and consisted in determining accurately the amount of water absorbed by gluten from solutions of varying concentrations of different acids, both with and without the presence of salts. The results of the experiments may be summarized as follows:

"Wheat gluten is an emulsoid colloid and shows all the properties of this class of compounds.

"Gluten absorbs water from dilute acid solutions, thereby losing its tenacity and ductility, becoming soft and gelatinous. The presence of small amounts of neutral salts in the dilute acid solutions inhibits water absorption by gluten."

The bread-making qualities of dough made from wheat flour depend upon the quantity and quality of the gluten it contains. The quality of the gluten is regulated by the kind and concentration of the acids and salts present in the dough. "If the kind and amounts of the acids and salts are such as to

favor water absorption, the quality of the gluten will be poor, whereas the presence of acids and salts in such amounts as tend to inhibit water absorption makes for an improved gluten."

The experiments showed that carbon dioxide-free water is the ideal washing agent for use in making gluten determinations.

The following standard method for gluten determinations is proposed by the authors: "Weigh 10 gm. of flour into a round-bottomed cup. Work into a stiff dough with freshly boiled distilled water and allow to stand under water for one hour. Then work in a stream of the distilled water for 14 minutes over a bolting-cloth frame, to catch any pieces which may fall. Then work in the fingers for one minute and weigh on a tared dish. The weight of dry gluten may be obtained after drying at 110° C. to constant weight. As a check, nitrogen determinations may be made on the dry gluten."

Turnips, beets, and other succulent roots, and their use as food, C. F. LANGWORTHY (*U. S. Dept. Agr. Bul. 503 (1917), pp. 18, figs. 4*).—This bulletin, which is prepared especially for housekeepers, extension workers, and teachers and students of home economics, presents data regarding the food value of the succulent roots, beets, celeriac, carrots, parsnips, salsify, radishes, turnips, kohlrabi, onions, garlic, etc., as well as of some of the less well-known root vegetables. There is also a discussion on the use of roots as condiments.

The nutritional value of the banana, V. C. MYERS and A. R. ROSE (*Jour. Amer. Med. Assoc., 68 (1917), No. 14, pp. 1022-1024*).—This article brings together and discusses experimental data regarding the ripening and chemical composition of bananas, and reports experimental data regarding the digestibility of the carbohydrates of bananas.

The utilization of the carbohydrates of the ripe, raw banana was found to be as good as that of the cooked foods employed in the control experiments. The ingestion of unripe bananas resulted in discomfort and discontinuance of the experiments at the end of the second day. When the bananas were not fully ripe there was considerable excretion of starch in the feces.

The authors pointed out that bananas "as sold in the market . . . are frequently not sufficiently ripe to be consumed to advantage immediately; and it would seem that gastro-intestinal disturbances when attributed to the banana were referable to this cause. . . . No ill effects, discomfort, or distaste were noted even after the consumption of large quantities of the ripe fruit for several days."

The experiments here reported showed that "much larger quantities of sugar (glucose, sucrose, levulose) may be given in the form of banana than as pure sugar (sucrose, glucose) without producing gastro-intestinal disturbances.

"The composition of the banana and the potato shows an interesting similarity both as regards total carbohydrate and the amounts of the different mineral constituents. While the banana can hardly be regarded as a potato substitute, the fact that it has practically the same caloric value as the potato is worthy of note.

"Of even greater importance is the fact that bananas may be eaten uncooked. This is of interest, in view of the increasing significance that is being attached to the thermolabile 'accessory food substances.'

"The banana would appear to be a particularly valuable food to employ in the dietetic treatment of nephritic patients with nitrogen retention. Very satisfactory results have been obtained in the rather mild cases of nephritis here reported."

[Germicidal effect of spices] (*Wisconsin Sta. Bul. 275 (1917), p. 46, fig. 1*).—Experiments at the station have shown that such spices as cinnamon, cloves, and

allspice have an inhibiting effect upon molds and bacteria, due to the essential oils which they contain. Molds were found to be more sensitive to these substances than were bacteria.

The nutritive value of agar agar and its use as a jellifying medium, C. R. FELLERS (*Pure Products*, 13 (1917), No. 4, pp. 177-185).—Data are given regarding the sources, preparation, use, and composition of agar agar, together with a discussion of the character of the carbohydrates present in it and the utilization of agar agar as a food.

A study of American beers and ales, L. M. TOLMAN and J. G. RILEY (*U. S. Dept. Agr. Bul.* 493 (1917), pp. 23).—A study of the composition of brewery products made in this country was carried out with the main object of finding, if possible, the means of distinguishing beers and ales made entirely from malt from those made from malt together with other products, such as rice, corn, and cerealin. The experiments were carried out under commercial conditions, with the cooperation of several breweries at which the samples of the product were taken at various stages of manufacture. From the analytical data which are reported in this bulletin the following conclusions are drawn:

"The all-malt beers made in this country contain higher percentages of protein than the all-malt beers made in Europe, owing to the use in this country of a barley high in protein.

"The use of rice, corn or corn products, and brewer's sugar as substitutes for malt reduces the content of protein, ash, and phosphoric acid in the finished beer. This difference, as regards the protein, ash, and phosphoric acid, is a sufficient basis for distinguishing the all-malt beers made in this country from those containing the commercial mixtures of rice, corn, cerealin, and brewer's sugar.

"It is necessary to calculate analytical results to the basis of a common wort in order to interpret them properly."

The vitamin content of brewers' yeast, A. SEIDELL (*Jour. Biol. Chem.*, 29 (1917), No. 2, pp. 145-154, figs. 4).—Feeding experiments with laboratory animals (pigeons) were conducted to determine the quantity of autolyzed yeast filtrate which is necessary to balance the deficiency of an exclusive diet of polished rice and also to compare the activity of dried yeast with that of the autolyzed material. The results are summarized as follows:

"In the case of pigeons, the vitamin deficiency of an exclusive diet of polished rice is just replaced by daily doses of from 0.5 to 1 cc. of the clear filtrate from autolyzed brewers' yeast. Doses of dried freshly pressed yeast approximately equivalent to 1 cc. doses of autolyzed yeast do not effectively replace the vitamin deficiency of a diet of polished rice.

"Of two samples of dried yeast, one of which was autolyzed previous to being dried and the other not, the pigeons receiving the latter lost weight on a polished-rice diet considerably more promptly than those receiving the former. The autolytic process therefore appears to influence favorably the activity of the vitamin of brewers' yeast.

"On the assumption that all the nitrogen contained in fuller's earth which has been shaken with autolyzed yeast filtrate is derived from vitamin, the maximum quantity of the latter which can be present in the original yeast filtrate is 0.18 gm. per 100 cc.

"The daily vitamin requirement of a grown pigeon is somewhat less than 1 mg. A diet containing 0.0033 per cent of vitamin, given in quantities ordinarily consumed by pigeons, will supply this requirement."

[Food and drug inspection] (*Bien. Rpt. Dept. Agr. Fla.*, 14 (1915-16), pp. 213, pls. 10, figs. 4).—This publication covers the work of the Division of Pure Food and Drugs, Stock Feed, Ferlitzers, and Citrus Fruits for the years 1915

and 1916. It contains the report of the district inspectors, the results of the testing of weights and measures, and extracts from laws, regulations, etc.

Cleaning silver by contact with aluminium in alkaline solution, H. L. LANG and C. F. WALTON, JR. (*Jour. Home Econ.*, 8 (1916), No. 8, pp. 418-421).—A brief report of the experimental work, which has been noted in full from another source (E. S. R., 36, p. 266).

[Report on] nutrition, T. B. OSBORNE and L. B. MENDEL (*Carnegie Inst. Washington Year Book*, 15 (1916), pp. 365-372).—This is a progress report (E. S. R., 34, p. 762) of an investigation by the authors of the relative nutritional value of different vegetable proteins. This included studies of the value of the proteins of corn and cottonseed products and the food hormones of yeast, as well as further investigations of protein-free milk. The results of most of these experiments have been noted from the original sources.

Lectures on nutrition delivered under the auspices of the Washington Academy of Sciences, Washington, D. C., 1916 (*Washington, D. C.: Wash. Acad. Sci.*, 1916, pp. [78], fig. 1).—This pamphlet contains reprints of the following five lectures, previously noted: The Biochemical Analysis of Nutrition, by C. L. Alsberg (E. S. R., 35, p. 368); The Basal Energy Requirement of Man, by E. F. DuBois (E. S. R., 35, p. 371); Food Economics, by G. Lusk (E. S. R., 35, p. 558); Studies on the Mineral Elements in Animal Nutrition, by E. B. Forbes (E. S. R., 35, p. 867); and The Importance of Vitamins in Relation to Nutrition in Health and Disease, by C. Voegtlin (E. S. R., 35, p. 861).

Studies in the physiology of the respiration.—I, The capacity of the air passages and the percentage of carbon dioxide in the alveolar air during rest and exercise, R. G. PEARCE (*Amer. Jour. Physiol.*, 43 (1917), No. 1, pp. 73-86, fig. 1).—The author proposes methods for calculating the dead space and the percentage of carbon dioxide in the expired alveolar air, for which the necessary data are obtained by determining the amount of air and the percentage of carbon dioxide in the air of a normal and a deep expiration. Using these methods, only a small variation in the dead space or the percentage of carbon dioxide could be determined between the conditions of rest and exercise consisting of walking at the rate of 3½ miles per hour.

Review of recent literature on conditions of abnormal metabolism in infants, J. L. GAMBLE (*Amer. Jour. Diseases Children*, 13 (1917), No. 4, pp. 362-389).—A summary and digest of recent contributions to the literature of acute and chronic disturbances of nutrition, acidosis, rickets, scorbutus, etc.

## ANIMAL PRODUCTION.

[Nutrition investigations at the Wisconsin Station] (*Wisconsin Sta. Bul.* 275 (1917), pp. 8-12, 13-17, figs. 7).—Notes on several studies are given.

Causes of bad effects of excessive wheat feeding, by E. B. Hart et al.—Earlier experiments (E. S. R., 33, p. 367) have shown that excessive feeding of wheat is decidedly injurious to cattle and swine. Further trials show that the effect of wheat feeding on the breeding capacity of cows is cumulative. No ill effect was apparent from such rations during the first gestation period, but when they were fed for two consecutive gestation periods or longer the offspring were born blind or weak. In other tests a ration containing a considerable amount of wheat embryo, but otherwise satisfactory, fed for only 60 days before parturition resulted in a characteristic weakness in the offspring.

Experiments with swine and rats indicated that the wheat embryo contains proteins of excellent character for growth, a large amount of the diet necessary water soluble B and a moderate amount of fat soluble A. Besides being deficient and unbalanced in mineral matter, however, wheat embryo contains a dis-

tinct toxic substance (the chemical nature of which is unknown) which may be largely extracted with ether along with the fat. When swine were fed a ration of wheat meal, wheat gluten, milk fat, and suitable salts they failed to grow after nine months and lost weight, finally showing difficulty in moving about, labored breathing, and muscular twitching. An examination of the spinal cord showed that the motor cells were shrunken, a condition similar to that produced in beri-beri.

*Effect of restricted rations on poultry*, by J. G. Halpin, E. B. Hart, and E. V. McCollum.—In experiments with poultry which have extended over a period of five years, it has been found that, while the death rate has been higher, fowls have made normal growth and produced fertile eggs on a wheat ration in most cases equally as well as on a corn ration. Young chicks fed cracked corn, green clover, and milk gained an average of 225.9 gm. in six weeks with no death loss; those fed wheat and green clover gained 58.8 gm., the death loss being 16 per cent; and those fed on corn and green clover gained 50.1 gm. with a higher death rate than those fed wheat and clover.

In a test of the effect of lime in the ration upon egg production, a scant supply of calcium has not caused the production of soft-shelled eggs, but has decreased the egg production. It is apparent that the hen draws upon her skeleton for the needed calcium when it is lacking in the ration.

*Crushed v. whole oats for work horses*, by F. B. Morrison, J. G. Fuller, and G. Bohstedt.—Tests for two winters with moderately worked horses showed no benefit from crushed oats during the first winter, but during the second winter the horses fed crushed oats and ear corn received 2 per cent less grain and gained 14.9 lbs. more per head in 18 weeks than those fed whole oats and ear corn. In a test with 18 hard-working horses during the spring and summer one horse in each team was fed whole oats and the other crushed oats, the horses fed crushed oats getting one-tenth less than the others. Both lots were fed the same amount of hay. At the end of 12 weeks the rations were reversed and continued for another 10 weeks. During the 24 weeks the horses fed crushed oats lost 38.5 lbs. each, and those fed whole oats lost 8.3 lbs. each, the results being similar during both periods.

*Forage crops for pigs*, by F. B. Morrison, J. G. Fuller, and G. Bohstedt.—In a test of forage crops v. dry lot for fattening pigs, rape pasture furnished excellent grazing throughout the experiment, July 20 to November 23. During this time the pigs on this forage gained 1.36 lbs. per head daily and required 3.77 lbs. shelled corn and 0.18 lb. tankage per pound of gain in addition to the rape. At 9.1 cts. per pound live weight for pork, 87 cts. per bushel for corn, and \$50 per ton for tankage, these pigs returned \$63.82 per acre of forage over the cost of concentrates. Another lot of the same number of pigs self-fed shelled corn and tankage on dry lot returned \$14.58 over the cost of the concentrates.

[*Feeding experiments with lambs*], by G. C. Humphrey, F. Kleinheinz, and F. B. Morrison.—In a comparison of roots and corn silage for wintering ewe lambs, three trials of 105 days each were made during 1912 to 1915. Each winter one lot of lambs received 2 lbs. of ruta-bagas, 2 lbs. of hay, and 0.37 lb. of oats and bran (3:1) per head daily, and the other lot received 1.8 lbs. silage, 1.8 lbs. hay, and the same amount of concentrates as the first lot. Each year the silage-fed lambs made better gains, the average being 0.14 lb. per head daily, while those fed roots averaged 0.11 lb. daily. The silage-fed lambs were fully as thrifty as those fed roots, and sheared slightly heavier fleeces.

During one winter one lot of lambs was fed 0.5 lb. per head daily of a mixture of gluten feed and whole oats (1:1), and another lot an equal amount of a mixture of wheat bran and oats (1:1). In addition each lot received corn

silage and clover hay. The lambs relished the gluten feed and oats mixture and gained a trifle more than those fed wheat bran and oats.

In a comparison of cottonseed meal *v.* linseed meal for fattening western lambs, 40 lambs were fed for 70 days a ration of 0.21 lb. of linseed meal, 1.12 lbs. of shelled corn, 2.75 lbs. of silage, and 0.83 lb. of hay, and another lot of 40 lambs was fed 0.16 lb. of choice cottonseed meal, 1.16 lbs. shelled corn, 2.75 lbs. silage, and 0.85 lb. of hay per head daily. The lambs fed linseed meal gained 0.365 lb. per head daily at a feed cost of 8.62 cts. per pound of gain, and those fed cottonseed meal gained 0.37 lb. at a feed cost of 8.42 cts. per pound of gain.

Experiments with sheep, E. J. RIGGS (*Ohio Sta. Bul. 303 (1916), pp. 176, 177*).—At the Washington County experiment farm, a comparison was made during the winter of 1914–15 of linseed meal and cottonseed meal in equal quantities as supplemental feeds for breeding ewes. No great differences were found between the feeds. However, the lot on cottonseed meal maintained their weight better and sheared 0.5 lb. of wool per head more than those fed linseed meal. The ewes fed linseed meal produced lambs that were heavier at birth than those fed cottonseed meal. At ten days of age and at the close of the experiment the lambs from the cottonseed meal fed ewes were heavier than the others.

Forage crops [for hogs], F. C. MINKLER (*New Jersey Stat. Rpt. 1915, pp. 67–73, pls. 2*).—Continuing experiments already noted (*E. S. R., 34, p. 172*) comparisons were made of different forage crops for swine.

It was found that where the animals were given their choice of forage crops brood sows nursing their young foraged quite as much on sweet clover as on alfalfa. Rape alone or rape and sweet clover were equally as palatable as alfalfa. Peas unaccompanied by oats or rape did not seem to attract the animals until they were more or less mature. It was noted that peas were more palatable when grown in the same area with oats and clover.

In case alfalfa is used as a forage with swine the area should be cut over at least twice during the season in order to increase its palatability and revitalize the plants. Light pasturage during the process of cutting alfalfa seemed to produce no injury to the stand.

Combination forage mixtures proved more useful and stable and produced more pork per unit of area than single forage crops. Pasturing forage crops early in the spring before the plants were 8 in. high proved to be an unsafe practice. It was found expedient to shut the animals out of the forage crop plats immediately following a heavy rain as a means of protection to the plants, and further to avoid injury from rooting by the animals. Where the combination mixture of oats, rape, peas, and clover was seeded and the areas not cropped close enough to prevent some of the oats from maturing a catch crop resulted and supplied palatable forage during the balance of the season.

A plat of 2.3 acres of rye, oats, Canada field peas, and sweet clover with grain supplement produced 781 lbs. of pork from May 11 to October 18 besides providing maintenance for 10 mature hogs from July 1 to October 18. A plat of 2.93 acres seeded to rye in the fall furnished green forage during the early spring for 18 gilts. On June 7 this plat was seeded to rape, soy beans, and sweet clover and provided maintenance for from 17 to 22 mature sows from August 12 to October 20, a small amount of green corn being fed as a supplement after October 1. An area of 4.76 acres of rye produced 1,270 lbs. of pork from April 20 to May 19, largely the result of young pigs running with their dams. This plat was then seeded to corn, and from the gleanings, after the corn was cut for silage with a corn harvesting machine, 30 shotes made a gain of 300 lbs. The yield of silage was about 11 tons per

acre. A plat of 0.26 acre of rape and sweet clover produced 215 lbs. of pork from nursing pigs from May 14 to October 12. Thirty head then grazed on this plat and fed 2,449.5 lbs. of a mixture of shelled corn, wheat middlings, and digester tankage in a self-feeder gained 772 lbs. A plat of 0.54 acre of rape, field peas, and sweet clover produced 1,050 lbs. of pork, furnishing green forage to 30 gilts during the whole summer. The gilts were also allowed 1 lb. of shelled corn per 100 lbs. live weight.

In all these experiments, unless otherwise stated, the animals were fed, in addition to the pasturage, 1 lb. of grain, chiefly corn middlings and tankage, per 100 lbs. live weight. Data on other grazing experiments are briefly reported.

[Problems relating to pork production] (*New Jersey Stas. Bul. 298 (1916), pp. 20-23*).—A mixture of rape and sweet clover in combination with oats as a protecting crop, with red clover added to secure permanence, had many advantages as a forage mixture for pigs. Rape alone was not very palatable. Soy beans with rape and sweet clover proved to be an excellent mixture, but furnished grazing for only a short time.

Experiments during the year indicated that pigs could be safely relied upon to select and balance their own rations. The use of the self-feeder shortened the growing and fattening period of pigs by at least 60 days. However, the use of the self-feeder in connection with grazing crops was not economical, especially for pigs under 100 lbs. in weight. It proved profitable for brood sows, nursing pigs, and fattening market hogs, but not for gilts intended for breeding or for market pigs during the entire cycle of their growing period. In wintering brood sows, it was found possible to maintain a 300-lb. sow on 3 lbs. of ground alfalfa hay per day, moistened with molasses and supplemented with a little hominy feed and tankage. The sows would eat only about 1 lb. of unground alfalfa hay per head daily.

Molasses was compared with corn and tankage as supplements for alfalfa hay for gilts. In this experiment five gilts fed molasses and alfalfa hay exclusively from the time they were weaned until after their first litter of pigs had been weaned, made their gains at slightly more than 3 cts. per pound less than those obtained with the five gilts fed corn, tankage, and alfalfa.

In spite of the fact that the entire station herd was subjected to the serum simultaneous treatment for the prevention of hog cholera, losses were frequent during the year and doubtful as to cause. That the double treatment under average conditions stunted the growth of pigs seemed well supported by conditions in the herd during the year. Losses were recorded among suckling pigs nursing immune sows although the sows were perfectly healthy.

The use of the self-feeder, F. C. MINKLER (*New Jersey Stas. Rpt. 1915, pp. 85-91, pls. 4*).—In the experiments here reported 50 shotes, 30 of which were pure-bred and 20 cross-bred, were fed for 77 days. Twenty of the animals were divided into four lots of 5 each and placed in dry lots 8 by 12 ft. with sleeping quarters in a protected building. Thirty head had the run of colony houses on a one-half acre plat of rape. Lot 1 in a dry lot and lot X (the 30 shotes in a rape field) were fed a mixture of shelled corn, wheat middlings, and digester tankage in self-feeders. Lot 2 was hand-fed the same mixture as a thick slop (100:38:12 by weight) in a dry lot. Lots 3 and 4 received shelled corn, molasses, and digester tankage, the former in the self-feeder and the latter by hand in the proportion of 100:40:15 by weight as a thick slop.

It was found that the pigs on the self-feeders consumed a surprisingly large amount of feed during the first few days of the test. All the animals went on full feed without difficulty or loss of appetite. The average daily gains per head were for lots 1 to 4 1.25, 0.73, 1, and 0.46 lbs., respectively, and for lot X

0.66 lb. The addition of molasses to a ration of corn and tankage did not reduce the cost or increase the efficiency of the mixture. Due in part to the interruption of hog cholera lot X did not make representative gains. The percentages of grain eaten by the self-feeder lots were as follows: Lot 1, corn 76, middlings 15, and tankage 9; lot 3, corn 82.6, tankage 13.5, and molasses 3.9; and lot X, corn 77.5, middlings 15, and tankage 7.5.

The advantages and disadvantages of self-feeders for hogs are discussed. They are recommended for use in feeding "brood sows nursing pigs, after the youngsters are 15 days old; pigs that have been weaned, provided they do not have access to a green forage crop; shotes that are being fattened either in dry lot, or forage crop, after they reach 100 lbs. live weight; and for fattening any animal in a dry lot where rapidity of gains is an advantage. The self-feeder should not be used for animals intended for breeding purposes as such animals will put on too much flesh and develop a tendency toward irregularity in their breeding propensities. Herd boars and sows that are being maintained preparatory for breeding should not have access to a self-feeder, for the practice will be expensive and a distinctive disadvantage unless the animals are out of condition and it is desired to put them in better flesh."

**Swine husbandry**, G. R. EASTWOOD (*Ohio Sta. Bul. 303 (1916), pp. 102, 103*).—In an experiment in hogging down rye at the Miami County experiment farm, 28 pigs, averaging 51.8 lbs., were grazed on two acres of a three-acre plat of rye for 38 days. In addition they were fed 0.25 lb. of tankage per head daily. They made a total gain of 459.5 lbs., or an average of 0.432 lb. per head daily, and consumed 5.71 lbs. of tankage per pound of gain. With pork at 8 cts., they made a net return of \$15.10 per acre, with no charge for labor. The acre of rye not grazed yielded 13 bu.

Some of the results of hogging down three three-acre plats of corn in the fall of 1915 are given in the following table:

*Results of tests of hogging down corn.*

Plat.	Estimated yield per acre.	Number of pigs.	Average initial weight per head.	Period.	Tankage consumed per acre.	Average gain.		Net profit (pork 8 cts. per pound).
						Per head daily.	Per acre.	
	<i>Bu.</i>		<i>Lbs.</i>	<i>Days.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	
1.....	39.9	57	92	22	104.50	1.52	635.5	\$48.23
2.....	49.7	62	121	18	92.91	1.57	584.5	44.44
3.....	48.8	60	153	18	90.00	1.66	596.8	45.49

**Report of the department of poultry husbandry**, H. R. LEWIS and W. C. THOMPSON (*New Jersey Stas. Rpt. 1915, pp. 93-120, pls. 10*).—An experiment with White Leghorn pullets to determine the value of sour skim milk as a supplement to the regulation New Jersey ration for laying fowls has been previously noted from another source (E. S. R., 35, p. 479). It is stated that the results of the experiment indicate that "egg producers can afford to pay from 20 to 45 cts. per 100 lbs. for sour skim milk."

In an experiment upon the relative feeding value of certain common sources of high protein-carrying feeds from both animal and vegetable sources, a progress report of which has already been noted (E. R. S., 34, p. 176), the birds receiving protein from an animal source, meat scrap, produced in the two years of the experiment a total of 8,501 eggs as compared with 4,710 by the soy-bean meal pen, 4,003 by the gluten feed pen, 2,847 by the linseed meal pen, and 2,995 by the cottonseed meal pen. The meat scrap pen laid 5,596 eggs during the first

year of the test. From the standpoints of egg production, general health of the fowls, and economy the protein from the animal source was the most proficient. The flock receiving cottonseed meal and linseed meal apparently broke down during the second year, when the mortality was comparatively high. The ration containing the soy bean meal was the most expensive, meat scrap second, gluten feed third, linseed meal fourth, and cotton-seed meal fifth.

In the experiment comparing a 25 per cent and a 10 per cent meat scrap ration for laying hens the results secured during the third year confirmed earlier conclusions that high egg production during the pullet year is apt to be followed by decreased production in future years. The flock receiving the 25 per cent meat scrap ration laid 6,711 eggs the first year, 4,207 the second year, and 3,014 the third year, as compared with 4,639 during the first year, 4,358 the second year, and 2,674 the third year for the flock receiving the 10 per cent meat scrap ration. The total profit derived from the egg production of these two pens for the three years was \$228.91 from the pen on 25 per cent meat scrap and \$166.69 from the other pen. It is concluded that "under systems of management where birds are kept for two laying years only, a higher percentage of meat scrap can undoubtedly be advised, as the increased production during the first year will more than balance the difference during the second year. No general bad effects were noticed from the use of 25 per cent meat scrap in the dry mash."

In experiments being conducted for the purpose of ascertaining the factors causing the variation in shade of the shell color of eggs it has been found that some hens produce eggs varying widely in shell color and others show marked uniformity in the same respect.

A progress report is made of experiments with two forms of egg preservatives. In tests of the first form of preservative, the basis of which is sodium silicate, the eggs were put down on March 10, one jar in a normal 10 per cent liquid silicate solution, a second jar in a similar solution using another commercial brand of silicate, a third jar in a strong alkaline solution, a fourth jar in a commercial egg preserver (1 lb. to 2 lbs. of water), and a fifth jar in the same egg preserver (1 lb. to 16 lbs. of water). On examination the following September no perceptible loss of weight had occurred in any one of the samples. No difference could be detected in taste of boiled eggs from each sample nor any variation from the normal egg other than settling of the yolks in some of the jars. The eggs in the alkaline solution were the least satisfactory.

The second form of preservative was in the form of a commercial ointment. Several dozen eggs were anointed with this material, wrapped in papers, and stored according to directions of the manufacturer. After four months the eggs were in splendid condition. Both of these sets of jars and crates of preserved eggs are to be examined further.

In experiments with White Leghorns the following advantages of February hatching were indicated: The farmer can give his chicks better care, as this work will come before the rush of the spring season. Cockerels will sell at a higher price as broilers, for the height of the broiler market is early in the spring. Chicks will make a good growth before hot weather comes. Cockerels for breeders reach big, strong development early in the season. The pullets will produce a large number of eggs when the older hens are in the molt and the prices are high. The high production during August, September, and October more than counterbalances the falling off in egg production during November and December. The females reach full maturity long before winter sets in with its cold days, and pullets may be used the following year as breeders.

**Influence of close inbreeding** (*Wisconsin Sta. Bul. 275 (1917), pp. 17, 18*).—**Studies on the influence of close inbreeding of fowls** (*E. S. R., 35, p. 564*)

indicate that under the unusually severe conditions of this experiment in-breeding has had distinctly detrimental effects. In 1913, 67 per cent of the fertile eggs from inbred stock hatched, while in 1916 only 18 per cent hatched. During this period the fertile eggs from check hens mated to inbred males decreased in hatching power from 67 to 64 per cent. Confirming previous results, the period of incubation was found to be lengthened in the case of the inbred flock.

There was a marked variation in the vitality of the inbred fowls, many of them being weak, while others made normal growth. In general the females were normal and the males frequently lacked vigor. It was also noted that a relatively larger number of inbred chicks failed to reach maturity.

**The production of eggs for hatching, H. ATWOOD** (*West Virginia Sta. Circ. 24 (1916), pp. 15*).—This is a brief review and list of experiment station and other literature bearing on the subject.

**The incubation of hen eggs, H. ATWOOD** (*West Virginia Sta. Circ. 25 (1917), pp. 24*).—This is a brief discussion of the general subject of incubation and a review of experiment station and other literature bearing thereon. The principles involved and the most improved methods in use at the present time are explained. A list of the literature cited is included.

**Brooding and feeding little chicks, H. ATWOOD** (*West Virginia Sta. Circ. 26 (1917), pp. 15, figs. 5*).—Full directions are briefly given.

**Turkey raising, A. S. WEIANT** (*U. S. Dept. Agr., Farmers' Bul. 791 (1917), pp. 26, figs. 16*).—Full directions are given for raising turkeys, the points discussed being the turkey industry in the United States, profits from turkey raising, varieties, management of breeding stock, incubation, brooding, fattening for market, caponizing, marketing, and diseases.

**Report of the department of biology, J. NELSON** (*New Jersey Stat. Rpt. 1915, pp. 239-242, 251-260*).—Observations on the periods of spawning and spatting of oysters in relation to weather conditions are briefly reviewed. Data on spawning at Tuckerton and on oyster plankton and oyster spatting at Edge Cove during 1915 are tabulated.

Results of investigations during the year show that Canadian oyster larvæ at the time of spatting are a fourth larger than those of native New Jersey oysters. The soft parts of an oyster occupy only about half of the shell cavity. An abundance of snails was found to be associated with a scarcity of oyster fry. The most accurate method for determining the number of oyster fry in a plankton sample is that of sedimentation.

Oysters exposed at low tide are delayed in spawning, and for those always covered the spawning is dependent on temperature. The length of the free larval life of oyster fry at 77° F. is 16 days; at 80°, 13 days. The temporary raising of the temperature of water by warm waves causes the fry to rise to the surface, while cold weather drives them down. Larvæ reared by artificial fertilization reach the shell stage in their development only when the fertilization is made within ten minutes after the oysters are taken out of the water. At 90° the shell stage is reached within 12 hours after fertilization. Larvæ tend to stay near the bottom at night, while they rise when daylight appears. The adult oyster discriminates in its food, rejecting what is unsuitable. The larval oyster swallows everything small enough.

## DAIRY FARMING—DAIRYING.

**Report of the department of dairy husbandry, A. S. COOK** (*New Jersey Stat. Rpt. 1915, pp. 125-141*).—Twelve cows in the early stages of lactation were divided into two lots of 6 cows each and fed for 100 days on the reversal

system to determine the value of cut alfalfa hay as a supplement for purchased grains. The lot fed the home-grown rations received alfalfa hay, silage, corn-and-cob meal, well cured alfalfa hay cut in a silage cutter, molasses, and soy bean meal. The other lot which was fed purchased rations received alfalfa hay, silage, corn meal, beet pulp, gluten feed, wheat bran, and cottonseed meal. The cows were so fed that each lot received about the same amount of dry matter and digestible nutrients. On the home-grown rations the cows produced 10,148.6 lbs. of milk and 350.6 lbs. of milk fat. Those on the purchased rations produced 10,125.7 lbs. of milk and 348.8 lbs. of milk fat. On the basis of market value the cost of the home-grown ration was \$110.83, making the feed cost per quart of milk 2.3 cts.; and of the purchased feeds \$120.17, or a feed cost per quart of milk of 2.5 cts. On the basis of cost of raising the feeds, the home-grown ration cost \$73.51, a feed cost per quart of milk of 1.5 cts. When the cows were fed all the alfalfa hay they would eat and 35 lbs. of silage daily they consumed 4.14 lbs. of cut alfalfa daily with the grain mixture.

The average cost of feed per cow in the station dairy herd during the year was \$100.97, as compared with \$95.24 for the previous year. No pasturage was available for the cows during the year, and as a result about 60 per cent of the total cost of feed was spent for roughage. For the 37 cows in the herd during the year the average 12-months' record was 7,671.9 lbs. of milk and 295.17 lbs. of milk fat. With feeds charged at market prices the feed cost of producing milk during the year was \$1.31 per 100 lbs. Charging roughage at cost of raising and concentrates at market value the feed cost of producing milk was 91 cts. per 100 lbs.

Data are given on the feed cost and gain in weight for heifer calves until freshening. Twenty Holstein heifers to an average age of 13½ months had consumed feed valued at \$46.94 each, and made an average daily gain of 1.64 lbs.; 7 Jersey heifers to an average age of 14½ months had eaten \$52.23 worth of feed each and gained 0.76 lb. each daily; 2 Guernsey heifers to an average age of 14½ months had consumed \$57.83 worth of feed each and made a daily gain of 0.96 lb.; 6 Ayrshire heifers to an average age of 17½ months had consumed \$65.81 worth of feed and made an average daily gain of 0.83 lb. per head; and a grade Shorthorn heifer had eaten \$37.68 worth of feed by the time it was 13 months old and gained an average of 0.84 lb. daily.

Notes are also given on cow testing association and advanced registry work.

Efficiency of various protein concentrates for milk production, E. B. HART and G. C. HUMPHREY (*Wisconsin Sta. Bul. 275 (1917), pp. 7, 8, fig. 1*).—Continuing experiments previously reported (*E. S. R., 35, p. 562*), trials were conducted during the year to determine the efficiency of such protein-rich concentrates as gluten feed, dried distillers' grains, and linseed meal when fed with a basal ration of corn meal, corn stover, and corn silage. For comparison, casein and skim milk powder were also tested. Holstein cows producing from 40 to 45 lbs. of milk per head daily were used, being fed each concentrate for four weeks. The protein in the ration was kept below the amount needed to keep the cows from losing nitrogen from their bodies in order to bring out any differences in efficiency of the various concentrates. The nutritive ratio of the rations was fixed at 1:8, and the proteins from the concentrates tested formed one-half of the digestible protein in the ration.

When fed with the basal ration used in these experiments, gluten feed showed a considerably lower efficiency than linseed meal, distillers' grains, and either casein or skim milk powder. In spite of the constant loss of

nitrogen from their bodies the cows were able to sustain the milk flow at a high level. However, the milk solids declined from 12 per cent at the beginning to about 10 per cent at the end of the test.

**Straw for growing dairy heifers, F. B. MORRISON, A. C. OOSTERHUIS, and G. BOHSTEDT** (*Wisconsin Sta. Bul. 275 (1917), pp. 12, 13*).—In an experiment lasting 98 days with dairy heifers, 9 heifers fed a daily ration of 8 lbs. of alfalfa hay, 20 lbs. of corn silage, 1.75 lbs. corn meal, 0.5 lb. of wheat bran, and 0.25 lb. of gluten feed gained an average of 0.97 lb. per head daily. Another lot of 9 heifers fed 7 lbs. of oat straw, 26 lbs. of corn silage, 1 lb. of choice cottonseed meal, 1.5 lbs. of gluten feed, and 0.5 lb. of wheat bran gained 0.93 lb. per head daily and were judged as thrifty as the others at the end of the test. These heifers ate only 4.5 lbs. of oat straw per head daily, the remainder being used for bedding.

**A study in the cost of producing milk on four dairy farms, located in Wisconsin, Michigan, Pennsylvania, and North Carolina, M. O. COOPER, C. M. BENNETT, and L. M. CHURCH** (*U. S. Dept. Agr. Bul. 501 (1917), pp. 35, figs. 8*).—By means of carefully kept cost accounting records covering from four to seven years, data have been procured on the cost of producing milk on four dairy farms of the better sort located in Dane County, Wis., McComb County, Mich., Chester County, Pa., and Edgecombe County, N. C. This bulletin outlines the problem of obtaining the complete cost of producing milk on these farms and shows the relationship among the various items making up the total cost, as indicated by the data procured. The items of cost were classified as feed and bedding, labor, use of building, use of equipment, use of bull, interest, depreciation, miscellaneous items, and overhead. The actual and percentage costs of each of these items are tabulated.

It was found that the actual cost of keeping a cow for one year on the Wisconsin farm was \$101.62, on the Michigan farm \$125.45, on the Pennsylvania farm \$103.12, and on the North Carolina farm \$127.76. The most important cost item was the expense for feed, this constituting on the Wisconsin, North Carolina, and Pennsylvania farms, where the herds depended largely upon pasturage for summer feed, approximately 50 per cent of the total cost, and on the Michigan farm, where the cattle were stall-fed throughout the year, 57.2 per cent of the total cost. The cost of labor was next in importance to that of feed, averaging approximately one-fourth of the total cost. This labor includes the work of men and horses required to feed and care for the cows, handle the milk, and market the products.

The total credits other than dairy products, such as value of manure, calves, and, in some cases, an appreciation in the value of the cows, ranged from \$12.27 to \$20.33 per cow. The average annual production of milk and milk fat per cow for the years for which complete and comparable data were secured was for the Wisconsin farm 5,240 lbs. of milk and 256 lbs. of fat; for the Michigan farm, 6,536 lbs. of milk and 293 lbs. of fat; for the Pennsylvania farm, 5,053 lbs. of milk and 207 lbs. of fat; and for the North Carolina farm 5,142 lbs. of milk. The net cost of production per 100 lbs. of milk was as follows: Wisconsin farm, \$1.52; Michigan farm, \$1.61; Pennsylvania farm, \$1.80; and North Carolina farm, \$2.16. It cost 31.2 cts. per pound to produce milk fat on the Wisconsin farm, 35.9 cts. on the Michigan farm, and 49.8 cts. on the Pennsylvania farm.

The results obtained in this study, together with data from other sources, are discussed in their bearing upon the production of milk throughout the country. The relation of milk production and the cost per cow to the cost per

100 lbs. of milk, based on data from 443 complete records on the four farms studied, is shown in the following table:

*Relation of amount of milk production and cost per cow to cost of milk production.*

Annual production of milk per cow.	Number of cows.	Production.	Average per cow per year.			Average per 100 lbs. of milk.	
			Feed cost.	Other cost.	Total cost.	Feed cost.	Total cost.
		<i>Lbs.</i>					
3,000 and under .....	16	2,349	\$43.93	\$39.97	\$83.90	\$1.87	\$3.57
3,001 to 4,000 .....	33	3,648	49.47	45.01	94.48	1.36	2.59
3,001 to 5,000 .....	78	4,596	55.00	50.04	105.04	1.20	2.29
4,001 to 6,000 .....	111	5,450	59.91	54.51	114.42	1.10	2.10
6,001 to 7,000 .....	109	6,445	62.85	57.18	120.03	.93	1.86
7,001 to 8,000 .....	60	7,514	70.38	64.04	134.42	.94	1.79
Over 8,000 .....	36	9,049	80.45	73.20	153.65	.89	1.70

"Though it cost more to keep a cow that gives a high yield than one giving a low yield, the unit cost of the milk produced fell as the yield per cow rose. This decrease in the cost of milk per pound was much greater in the step from the poor cow to the cow of fair quality than in the step from the fairly efficient cow to the good cow or to the exceptional cow. Thus, from the standpoint of economic milk production, it appears that the first step in building up a poor dairy herd (that is, replacing scrubs with grades) is not merely the easiest step but also the one which promises the most for a given expenditure of money and labor."

**Dairying industry of Ontario, G. R. TAGGART** (*U. S. Dept. Com., Com. Rpts., No. 25 (1917), pp. 394, 395*).—Statistics are given of the number of dairy cattle and the production, exportation, and prices of dairy products in Ontario in 1915 and 1916. A brief description of a patent cheese box designed to prevent breakage in the shipment of cheese is also given.

Third report of the commission on milk standards appointed by the New York Milk Committee (*Pub. Health Rpts. [U. S.], 32 (1917), No. 7, pp. 271-296*).—This report deals briefly with the purposes and means of enforcement of milk standards and the grading of milk. Summaries covering a period of five years are given of the more important conclusions reached by the commission on chemical standards for milk bacteria and bacterial testing, pasteurization, grades of milk, cream, butter, ice cream, condensed milk, skim milk, and buttermilk, clarification, homogenization, licenses, and labeling. Appendixes give factors of primary importance in dairy practice for controlling the sanitary character of milk and a history of the commission.

**Milk and cream regulations, I. C. WELD ET AL.** (*Hoard's Dairyman, 53 (1917), No. 4, pp. 132, 160, 161, fig. 1*).—This report of the committee on milk and cream regulations, read before the Springfield, Mass., meeting of the Official Dairy Instructors' Association, gives the results of a study of the milk and cream regulations of 694 cities and towns in the United States. Complete regulations were obtained from 409 cities and towns and partially complete regulations from 62, while 223 cities, for the most part containing from 5,000 to 25,000 population and located in 45 States, reported that they had no regulations pertaining to the sale of milk and cream.

It is concluded that "there is a great and urgent need for further research and study on the part of our dairy investigators of some of the problems involved in the production and handling of milk, and . . . that definite in-

formation now available be placed in the hands of all who are responsible for the laws and ordinances governing the production, transportation, handling, and sale of milk."

The advantages of a carbohydrate medium in the routine bacterial examination of milk, J. M. SHERMAN (*Jour. Bact.*, 1 (1916), No. 5, pp. 481-488, pls. 2, figs. 3).—A study is reported of bacterial counts made on plain agar prepared according to the standard formula and on lactose agar with the same ingredients plus 1 per cent of lactose. Triplicate plates were made for each dilution and the counts were made after 48 hours' incubation at 37° C.

Results obtained from 18 samples of raw market milk showed an average increase of 43 per cent in the counts obtained with lactose agar over those obtained from plain agar. Fourteen of these samples showed an increase of over 20 per cent in favor of lactose agar. Data obtained from the examination of six samples of pasteurized milk showed increases of 141 to 1,050 per cent in favor of lactose agar. The average diameter of the ten largest colonies on plates from one culture of *Bacterium lactis acidi* was 64  $\mu$  on plain agar and 614  $\mu$  on lactose agar; for another culture of this organism 284  $\mu$  on plain agar and 833  $\mu$  on lactose; and for a streptococcus 228  $\mu$  on plain agar and 536  $\mu$  on lactose.

The carbohydrate medium was found to be of considerable value in differentiating the types of organisms on the plates.

A. T. C. classimeter, A. T. CHARRON (*Rpt. Min. Agr. Prov. Quebec, 1916, pp. 91-94, figs. 4*).—A simple apparatus for the rapid classification of milk and cream on the basis of acid content is briefly described and directions are given for its use.

The effect of feeding on the composition of butter: Decorticated groundnut cake and decorticated cotton cake, H. T. CRANFIELD (*Analyst, 41 (1916), No. 488, pp. 336-339*).—Experiments carried out at the Midland Agricultural and Dairy College upon the effects on the composition of butter of feeding peanut cake and cottonseed cake are reported. Analyses are given of the two cakes.

Eight cows were fed for five weeks a basal ration of mangels, hay, bran, and dried yeast. In addition 4 of the cows were fed 4 lbs. of decorticated peanut cake and the others 4 lbs. of decorticated cottonseed cake per head daily. The fat of the butter made from the mixed milk from each set of cows, taken night and morning on alternate days, was subjected to analysis.

No great differences were found in the composition of the butter fat produced by the two groups except in the proportion of unsaturated fats, which appeared to be somewhat greater in the samples of butter produced from the peanut cake feeding. The butter from peanut cake feeding was much softer and usually rather darker in color than that from cottonseed cake. No special differences were noticeable in flavor of the two butters.

Why gelatin is required and its effect on quality [of ice cream], O. E. WILLIAMS (*Milk Dealer, 6 (1917), No. 5, pp. 18-21*).—Brief consideration is given to the use of gelatin in ice cream making, together with results of experiments conducted by the Dairy Division of the U. S. Department of Agriculture relative to the effect of gelatin on the quality of ice cream.

It was found that in some cases gelatin produced undesirable aftertastes. Some grades of gelatin seemed to accelerate and blend the cream and fruit flavor of the ice cream. Where too much gelatin was used the fruit flavor was not so pronounced. Gelatin that had been heated repeatedly produced ice cream having a weak body. The best results were secured when the gelatin was used the same day it was prepared and at a temperature of at least 160° F. before it was mixed with the cold cream.

Ice cream made from homogenized cream was packed in 3-gal. cans in an ordinary ice cream cabinet in a warm room. At the end of 48 hours the ice cream containing no gelatin had completely lost its identity and value as ice cream, while that containing a normal amount of gelatin was practically unchanged. Two cans of this ice cream were kept under favorable storage conditions for six months, at which time the flavor and texture of the gelatin was good and the more preferable of the two.

Correct payment for cheese factory milk by the Babcock test, J. L. SAMMIS (*Wisconsin Sta. Bul.* 276 (1917), pp. 42, figs. 4).—In this bulletin various methods for computing milk payments from the fat test at cheese factories are explained and illustrated by using each method for calculating payments for milk to a set of five factory patrons who deliver milk varying in fat content from 3 to 5 per cent. The payments are then compared with the values for the five lots of milk reckoned on the average yield of cheese of known moisture content, as determined by over 300 experiments and factory tests made by the New York State Station (E. S. R., 4, p. 948).

It was found in 94.97 per cent of 15,000 cases studied that the patrons' payments computed by the fat test were correct within 2 cts. on the dollar. In all cases a new method by which the weight of milk is multiplied by the percentage of fat plus 0.6 gave results within 2 per cent of the actual yield. Other methods were studied which also gave accurate results, but it is stated that the fat plus 0.6 method is the simplest and is therefore preferred for practical use. The pooling system is condemned.

Because of a belief that the percentage of casein in milk is not closely enough related to the percentage of fat to permit the use of a formula for calculating casein, the Hart casein test has been used at some factories in addition to the Babcock test as a basis of payment. Studies of over 2,200 payments to patrons of Wisconsin cheese factories showed that to a very considerable extent the variations in the results of using this test from month to month offset each other, so that the net gain at the end of the year was small in the great majority of cases. In view of the fact that the relative cheese-making value of different lots of milk depends upon the cheese-making solids which they contain, and is independent of the percentage of moisture in the cheese, the new method of computing payments is deemed equally applicable at Cheddar, Swiss, brick, and Limburger factories where whole milk cheese is manufactured and where the whey fat is recovered by skimming.

Comparison of the imported and domestic Swiss cheese, J. L. SAMMIS (*Wisconsin Sta. Bul.* 275 (1917), p. 44).—Results of analyses indicate that the average of 39 samples of imported Swiss cheese contained 49.8 per cent of fat, while the average of 48 samples of the domestic product was 52.04 per cent of fat. It is stated that the main difference between imported and domestic cheese seems to be due to the time and manner of curing. The imported product is held for six months or more before it is consumed, whereas the domestic cheese is usually sold or put into cold storage within a month or two from the time it is made. "Without long-continued curing and salting in a warm room, the quality of domestic Swiss cheese can not equal that of the imported product."

Effect of silage on quality of Swiss cheese, J. L. SAMMIS (*Wisconsin Sta. Bul.* 275 (1917), p. 45).—Results of experiments at the university creamery and of field studies indicate that, by proper cleanliness in feeding silage and handling the milk, it is possible to avoid cheese troubles due to the feeding of silage. An examination of the product of a number of factories producing block Swiss cheese from milk secured from silage-fed cows indicated that a good quality of cheese was generally secured. In some cases gassy fermentations affected

the quality of the milk, causing bloating of the cheese, but this was found to be due to the fact that infection came from the whey tank and was transmitted to the next day's milk through the use of the same cans for whey and milk.

**Cheese making in Vermont**, H. B. ELLENBERGER (*Bul. Vt. Dept. Agr., No. 25 (1916), pp. 31, figs. 3*).—In addition to statistical notes on the cheese industry in the State, suggestions are given for the manufacture of cheese under Vermont conditions. A floor plan for a cheese factory to handle up to 12,000 lbs. of milk is shown.

**Skimming whey at Vermont cheese factories**, H. B. ELLENBERGER and M. R. TOLSTRUP (*Bul. Vt. Dept. Agr., No. 26 (1916), pp. 10*).—Brief directions are given for the skimming of whey and the manufacture of whey butter at cheese factories. Results of three years' work at a small Vermont cheese factory show that 2½ lbs. of whey butter were made per 1,000 lbs. of milk, the net receipts to patrons being 4.6 cts. per 100 lbs. of milk.

**The pasteurization of skim milk and whey as food for calves**, V. A. MOORE (*N. Y. Dept. Agr. Bul. 81 (1916), pp. 1780-1797, pl. 1*).—This paper deals with the subject from the standpoints of the prevention of the spread of the germs of infectious diseases through milk and whey and the dietetics of heated milk. An appendix gives tabulated results of experiments by various workers on the thermal death point of tubercle bacilli. A bibliography is included.

## VETERINARY MEDICINE.

**Anaphylaxis to the separated proteins of horse serum**, H. H. DALE and P. HARTLEY (*Biochem. Jour., 10 (1916), No. 3, pp. 408-433, figs. 10*).—From the study the authors conclude that each of the three proteins, euglobulin, pseudoglobulin, and albumin, separable from horse serum by their physical and chemical properties, can act as anaphylactic antigen. A guinea pig which has been sensitized by one of the proteins is more sensitive to that than to either of the others from the same serum. In some cases the sensitization appeared to be rigidly specific.

The sensitiveness of the guinea pig to albumin is developed later than is that to the globulins. This difference possibly accounts for the fact that previous investigators failed to detect the sensitizing property of albumin. The difference is especially marked when sensitization is carried out with the whole serum.

An effective dose of any of the proteins to which the guinea pig's plain muscles have been sensitized partially or completely desensitizes it to the other proteins of the same serum. No distinction of antigenic properties was shown by the crystalline albumins of the white of the eggs of hens and ducks.

The results are discussed in detail and are deemed of practical value in concentrating the curative element in a specific immune serum, where the ideal is "simply the reduction of the ratio of total protein to antitoxic value; for the purpose of reducing serum reactions the elimination of albumin seems to be as important as that of euglobulin, when the pseudoglobulin is the fraction carrying the therapeutic power." A relatively long latent period of the sensitiveness to albumin is considered to represent the successive appearance, at different time intervals, of sensitiveness to the different serum proteins rather than as representing separate reactions to the sera of the different animals which may have contributed to the serum.

**The action of hypochlorites and allied substances on proteins, and their behavior on injection**, T. H. MILROY (*Biochem. Jour., 10 (1916), No. 3, pp. 453-465, figs. 5*).—Experiments are reported in graphical form and discussed on the

action of hypochlorites on albuminous solutions, the action of chloramin-T on albumins, the action of hypochlorites and chloramin-T on amino acids, intravenous injections of hypochlorites and chloramin-T, and chloramin-T injections.

The effect of various chemical substances on the hemolytic reaction, N. P. SHERWOOD (*Jour. Infect. Diseases*, 20 (1917), No. 2, pp. 185-200).—Data obtained from the investigation of the effect of lactic acid, hydrochloric acid, sodium bicarbonate, and acetone on the complement content of rabbits in vivo; of ether and chloroform anesthesia on the hydrogen ion concentration and complement content of the blood of normal rabbits; and of the influence of carbon dioxide, lactic acid, hydrochloric acid, uric acid, urea, benzoic acid, tartaric acid, hydrazin sulphate, acetic acid, acetone, ether, and chloroform on the hemolytic reaction in vitro are reported in detail and discussed.

The data show an apparent drop in complement as a result of anesthesia. This, however, was found not to be constant. "The apparent drop probably is the result of the presence of the anesthetic, as well as of a slight increase in acidity. Sodium bicarbonate and lactic acid injected into rabbits did not cause a drop in complement; if anything, they caused an increase. The lactic acid was probably oxidized over into carbonates by the body, thereafter acting as an alkali." Hydrochloric acid injected into rabbits caused a marked drop in complement. This is considered to be due to the nonoxidizability of the mineral acids in the body. Acetone injected in fairly large amounts failed to cause a drop in complement.

Carbon dioxide, lactic acid, hydrochloric acid, urea, benzoic acid, tartaric acid, acetic acid, acetone, ether, chloroform, and hydrazin sulphate were found to defect or destroy hemolytic complement in certain concentrations. All of these agents except urea and carbon dioxide caused a linking of human red blood cells in certain concentrations.

"In general it may be said that the zone of concentrations fixing complement very nearly approximates, and in many cases coincides with, the weakest dilutions producing hemolysis, and may extend down to include a few concentrations which are unable to produce hemolysis. The amount present in the blood is normally many times less than the amount required to affect complement. Under some pathologic conditions the concentration in the blood may be greatly increased, nearly approaching the amount which would affect complement."

It is indicated in the case of the anesthetics that there is "a twofold mechanism inhibiting hemolysis by amboceptor and complement—the action of the anesthetic on the permeability of the membrane, and the deflection of complement." The possibility that "some organic compounds might occasionally play some rôle in either inhibiting or intensifying the anaphylactic shock, since complement seems to be involved in this reaction," is suggested.

The passive transference of nonspecific antibodies, P. K. OLITSKY and B. S. DENZER (*Jour. Infect. Diseases*, 20 (1917), No. 2, pp. 145-150, figs. 5).—Experiments are reported in which one rabbit was repeatedly inoculated with increasing doses of dead typhoid bacilli grown on agar slant and another animal similarly inoculated with organisms of the same strain but grown on serum media. Care was taken to exclude particles of the media from the suspension used for inoculation. Ten days after the last injection blood was obtained from the animals and in the first case designated as "plain-agar typhoid immune serum" and in the second as "serum-agar typhoid immune serum." Guinea pigs were sensitized to these sera and later killed, and the uterus removed and tested in Locke's solution according to the procedure of Dale.

In the case of the guinea pig injected with plain typhoid immune serum the uterus had absorbed typhoid antibodies but there was no reaction to serum. In

the case of the guinea pig injected with serum typhoid immune serum the uteri had absorbed typhoid antibodies and at the same time antibodies against human serum.

The practical significance of the experiments reported is "that great care should be exercised in classifying bacteria by the ordinary method of testing against rabbit immune serum."

A comparative examination of the blood of certain Australian animals, G. BUCHANAN (*Proc. Roy. Soc. Victoria, n. ser., 28 (1916), No. 2, pp. 183-207, pls. 2*).—The author has examined the blood of various Australian batrachians, reptiles, birds, mammals, and one fish, and reports the results in tabular form, together with a brief discussion of the data.

In general a decrease in size and an increase in the number of the red cells was found in ascending through the various vertebrate groups. There was also a corresponding decrease in the number but an increase in the size of the lymphocytes. The mononuclears remained fairly constant in size but decreased in numbers. The polymorphs also increased in percentage counts with the rise in the scale of vertebrates. The eosinophils were really numerous only in birds and the higher reptiles, where there were also two kinds of granules, a round and a crystalloid variety, possibly pointing to an avian relationship. Mast cells were absent in the fish.

The occurrence in nature of certain yeast-like fungi with reference to their possible pathogenicity in the higher animals, W. H. EMIG (*Ann. Missouri Bot. Gard., 3 (1916), No. 2, pp. 243-307, figs. 13*).—From 850 different sources, 180 cultures of yeast-like fungi were obtained, but only 12 of these grew on a blood serum medium at 37° C. The 12 fungi included 6 cultures of *Torula*, 5 of *Alternaria*, and 1 of *Oospora*. One culture of *Torula* and 4 of *Alternaria* produced small quantities of alcohol in sugar nutrient solutions.

In acid yeast-water solutions all 12 of these organisms brought about a change in the acidity reaction, there being a decrease in the acidity of all the acid nutrient solutions except in the presence of acetic acid and in one culture.

"The results of 34 animal experiments were negative in that the death of certain animals was not caused by the formation of lesions or abnormalities due to the organisms injected. No extracellular toxins were obtained from the cultures of these 12 yeast-like organisms.

"The results of these experiments and a review of literature on animal pathology indicate either that pathogenic yeast-like fungi do not occur in nature, or that, if they are present, they are so few as to be met with only under exceptional conditions."

Reports of the civil veterinary department, Assam, for the years 1914-15 and 1915-16, W. HARRIS (*Rpt. Civ. Vet. Dept. Assam, 1914-15, pp. 28; 1915-16, pp. 29*).—The usual annual reports (E. S. R., 32, p. 81).

Annual reports of the civil veterinary department, Bihar and Orissa, for the years 1914-15 and 1915-16, D. QUINLAN (*Ann. Rpt. Civ. Vet. Dept. Bihar and Orissa, 1914-15, pp. 15+XIV+2; 1915-16, pp. 15+XVI+2*).—The usual annual reports (E. S. R., 32, p. 272).

Report on the civil veterinary department (including the Insein Veterinary School), Burma, for the year ending March 31, 1916, G. H. EVANS (*Ann. Rpt. Civ. Vet. Dept. Burma, 1916, pp. 7+15, pl. 1*).—The usual annual report (E. S. R., 34, p. 275).

Regulations adopted by the Live Stock Sanitary Board and the live stock sanitary law of Alabama, 1916 (*Auburn, Ala.: State, pp. 28*).—The text is given.

Notes on fowl pest (pestis avium) and foot-and-mouth disease, S. BELFANTI and A. ASCOLI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 39 (1916), No. 19, pp.*

577-597, pl. 1).—Detailed tabular experimental data of a number of inoculation experiments with the virus of fowl pest in varying dilutions are submitted. The defibrinated blood of a fowl which had died from the disease was found to cause marked temperature rises but not to confer immunity.

Data obtained from immunization experiments against foot-and-mouth disease are also reported. The bovine virus was found to cause febrile manifestations and stomatic lesions in swine in two days. The material obtained from the stomatic vesicle mixed with blood and kept in a thermostat for five days did not cause any stomatic manifestations, and conferred immunity only in the presence of bovine or porcine virus. The results reported are considered to be merely preliminary, and no definite conclusions are drawn.

Comparative study of *Bacillus anthracis-symptomatici* and allied organisms with respect to gas production, L. C. TODD (*Jour. Infect. Diseases*, 20 (1917), No. 2, pp. 151-169).—Detailed tabulated experimental data obtained from a comparison of results in gas production from sugars by *B. anthracis-symptomatici* and allied organisms show that the organism produces more gas from dextrose, levulose, and maltose than *B. oedematis-maligni*. The greater proportion of this gas is carbon dioxid. The training of seed cultures was found to influence the gas production of these organisms considerably.

"Substances credited with the putrid odor are produced in cultures by strain members of both groups. The gas production of most of the strains occurs late and progressively up to about the tenth day. In some media gas production continues to a slight degree for some time after this. An explosive mixture of gases, apparently containing hydrogen and no carbon dioxid, may be produced from 'carbohydrate-free' broth."

The conglutination reaction in the diagnosis of glanders compared to other diagnostic methods, G. B. SCOTT (*Mod. Zooiatro, Parte Sci.*, 27 (1916), Nos. 9, pp. 213-224; 10, pp. 246-256).—The author concludes that the conglutination test is the most desirable for the diagnosis of glanders. The results are in accordance with those obtained by complement deviation but the conglutination procedure is preferred.

The precipitin reaction is considered to present certain possible sources of error which depend largely on the technique. The intrapalpebral reaction is deemed a very accurate diagnostic procedure.

The ophthalmic reaction was found not always to yield reliable results. Its positive reactions are of value, but the negative ones do not necessarily exclude infection. Repeated instillations of mallein can not always be relied upon to reveal infection. On account of the ease of recognizing positive results the reaction is considered of value as a subsidiary test.

Piroplasmosis and other parasite diseases of the blood of domestic animals in the Balkans, W. N. MARKOFF (*Arch. Schiffs u. Tropen Hyg.*, 20 (1916), No. 14, pp. 313-335; *abs. in Trop. Vet. Bul.*, 4 (1916), No. 4, pp. 151-154).—This report of observations made for the most part during 1912 to 1914 at various places in the Balkans relates particularly to protozoan diseases.

The reliability of cell proliferative changes in the diagnosis of rabies, J. B. HARDENBERGH and B. M. UNDERHILL (*Penn. Live Stock Sanit. Bd. Circ.* 46 (1916), pp. 10, figs. 6).—Previously noted from another source (*E. S. R.*, 36, p. 80).

Rabies eradication in Nevada, S. E. PIPEB and E. R. SANS (*Carson City: Nevada Rabies Com.*, 1916, pp. 7, figs. 2).—This is a report upon the progress of the rabies eradication campaign carried on under the direction of the Bureau of Biological Survey of the U. S. Department of Agriculture in cooperation with the Nevada Rabies Commission.

Draft of proposed law for immunization of cattle and carabao in the Philippine Islands and correspondence relative to such immunization, H. S. MARTIN (*Manila, P. I.: Dept. Pub. Instr., 1915, pp. 29*).—This is a detailed draft of the proposed law in both English and Spanish.

A further report of the diagnosis of open cases of tuberculosis, D. H. UDALL and R. R. BIRCH (*Cornell Vet., 7 (1917), No. 1, pp. 13-29*).—The results of a study carried out to demonstrate the possibility of recognizing open cases, or "spreaders," of the disease, covering a period of about six years, are reported in detail and discussed.

Reliance upon a physical examination alone for the suppression of the disease is considered to be a failure from the results obtained. It is, however, of value in the partial reduction of the number of "spreaders" in a badly infected herd. It is also considered to be of service in detecting the occasional nonreacting "spreader."

A uniform standardized system of inspection is recommended.

Tuberculosis of fowls (*Wisconsin Sta. Bul. 275 (1917), pp. 40, 41*).—Experiments on the communicability of avian tuberculosis to swine by inoculation of pure cultures of the avian organism, by B. A. Beach, E. G. Hastings, and J. G. Halpin, are noted. Fatal results were obtained in every case, although it is considered that the post-mortem examination would have hardly indicated that the changes were due to the tubercle bacillus. "While these cases of fatal tuberculosis were produced in hogs by artificial inoculation, it is doubtful whether the avian tubercle is able to produce a fatal termination of the disease when the infection is acquired under natural conditions, as by feeding."

The "wattle" test with avian tuberculin was found to be highly satisfactory.

Special report on diseases of cattle (*U. S. Dept. Agr., Bur. Anim. Indus., 1916, rev. ed., pp. 568, pls. 50, figs. 29*).—A revised edition of the work previously noted (*E. S. R., 21, p. 283*).

Some facts about abortion disease, E. C. SCHROEDER and W. E. COTTON (*Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 321-330*).—A paper, presented at the meeting of the Massachusetts Veterinary Medical Association, at Springfield, Mass., in October, 1916, in which the authors discuss some of the results of their recent work.

Since the *Bacillus abortus* is an obligatory parasite, its chronic persistence in the bodies of infected cows is probably the most important among the causes responsible for the propagation, perpetuation, and wide prevalence of the disease. In numerous tests made with milk from many different cows the abortion bacillus was never found in the milk of a cow unless both her milk and her blood serum possessed agglutinating properties for suspensions of abortion bacilli. This, however, does not necessarily mean that the milk of all cows which react with the agglutination test for abortion disease is infected, since tests of milk from reacting cows have been made without detecting abortion bacilli.

Investigations thus far indicate that the blood serum of reacting cows with uninfected udders gradually loses its power to agglutinate suspensions of abortion bacilli. If this proves to be the case, it is held that with other facts it will justify the conclusion that the persistence of agglutinating and complement-fixing substances in the blood of cows, relative to abortion disease, is intimately associated with the abortion bacilli that enter that body through the lymphatics from infected udders. That abortion bacilli do not maintain themselves in the bodies of cows elsewhere than their udders and gravid uteruses is a contention for which they have obtained fairly convincing proof. The authors consider the evidence at hand sufficient to prove that abortion bacilli do not main-

tain themselves in the bodies of nonpregnant cows elsewhere than in their udders.

Investigations of seemingly vigorous, healthy calves produced by cows with infected udders have shown that such calves may harbor abortion bacilli in their stomachs and gastro-hepatic lymph glands, but invariably when the calves were infected the afterbirth and the uteruses of their dams were also infected with the disease.

The authors find that the agglutination test for abortion disease is fully as reliable as the complement-fixation test, but far less complex, and hence, in the hands of those who have many and varied duties, more reliable. The introduction of abortion bacilli into the udder through the teat, though a method of injection was used which almost certainly precluded mechanical injury, positively infected it and caused the gradual development of agglutinating power for suspensions of abortion bacilli in the blood serum. The passage of abortion bacilli from the udder to the uterus is held to be an experimentally demonstrated fact.

The present status of the abortion question, A. EICHHORN and G. M. POTTER (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 3, pp. 295-320).—The data given in this paper, presented at the meeting of the American Veterinary Medical Association, at Detroit, Mich., August 22, 1916, are based upon investigations carried on by the U. S. Department of Agriculture.

In discussing the difficulties met with in their investigations of contagious abortion of cattle, reference is made to the new type of the organism which occurs in the milk of certain cows, recently described by Alice Evans (*E. S. R.*, 35, p. 675), and to which the name *Bacillus abortus lipolyticus* is given because it decomposes butter fat. This type has failed to react to the agglutination and complement-fixation tests and feeding and inoculation tests have also been inconclusive. A strain of *B. abortus* from pathogenic sources after having grown for 9.5 months in a medium containing milk fat acquired the same fat-splitting property.

In several herds where abortions have occurred occasionally repeated serological tests have failed to demonstrate the presence of *B. abortus*. Whether these organisms play a causative rôle in such cases; whether they are attenuated forms of the pathogenic variety which have lost some of their characteristics as they acquired the fat-splitting property, and if so, whether under certain circumstances they may not regain their pathogenic properties; and whether they are detrimental to human health are questions that remain to be determined.

The authors' experience leads them to believe that there may be some organism of which nothing is known at the present time that may eventually be found to cause abortion in at least part of those cases (some 5 per cent) now recognized as nonspecific abortion.

In a discussion of immunity the authors state that even among young cows abortion occurs but once in much more than 50 per cent of the cases. Whether this be called immunity or by some other name there is unquestionably some protective agency that for all practical purposes must be recognized as an acquired resistance against the disease. In a large herd at Washington, D. C., where investigations have been carried on, abortions were frequent while new cows were being purchased and susceptible material thus added, but as the practice was discontinued and the calves born in the herd were raised the disease progressively decreased, until at the present time abortion is rare and a definite herd immunity seems to have been established.

The authors find that serological tests are not infallible, due to the fact that both the infected animals and the immune ones which no longer harbor the

causative organism in their bodies may react. It is also pointed out that a reaction does not necessarily indicate that the animal has aborted or that it will abort, since the immunity may have been acquired without the occurrence of any visible manifestations. Also an aborting cow may sometimes fail to react.

In discussing the time and method of infection the authors report upon agglutination tests made of the blood of the female cattle of breeding age in a herd consisting of more than 2,000 head of Jerseys, of which about one-third were pure-breds and the remainder grades. Of the 413 cows which had produced calves 159, or 38.5 per cent, aborted and of these 120 aborted once, 35 twice, and 4 three times. Fifty-eight of the cows which aborted once gave a positive reaction and 8 were questionable, and of these 66, 9 showed difficulty in breeding. Fifty-four aborters gave negative reactions and 3 showed difficulty in breeding. Of the 35 which aborted twice, 27 were positive and 3 questionable, and of these 2 showed difficulty in breeding; 5 gave negative results and showed no difficulty in breeding. Of the 4 cows which aborted three times, 3 reacted positively and 1 negatively, but no difficulty in breeding was recorded. Twenty-five cows showed difficulty in breeding without aborting, and of this number 10 gave positive reactions, 12 negative, and 3 questionable. Sixty-six reacted positively without showing other evidence of infection. The facts presented seem to contradict strongly the contention that infection is to a considerable degree acquired during calthood.

With a view to determining the degree to which calves and bulls are infected, numerous samples of blood were collected at the abattoirs of Baltimore, Philadelphia, Washington, and Richmond from animals of dairy breeding. There were tested 182 bulls over one year of age, of which 10 were positive and 6 were questionable. Of 520 male calves up to one year of age 7 gave positive and 4 gave questionable reactions, and of 299 female calves of like age 2 positive and 2 questionable reactions were obtained.

The authors' conclusion in regard to immunization is that at present such treatment should be regarded as second in importance to proper sanitation. In referring to medicinal preparations, including proprietary remedies, it is pointed out that there is no supporting evidence available for any of such preparations. Inasmuch as there is no therapeutic treatment known at present which will either prevent or cure infectious abortion, attention should be primarily directed toward prevention by sanitation. Suggestions are given as to the control of abortion, together with a discussion of methods of disinfection.

Contagious abortion of cattle, A. EICHHORN and G. M. POTTER (*U. S. Dept. Agr., Farmers' Bul. 790 (1917), pp. 12*).—A general account of the disease and its treatment. It is pointed out that while formerly confined almost entirely to dairy cows it has now spread to the beef herds on the range, where the losses are proving especially severe. The stockmen, as well as the dairymen, are urged to awake to the seriousness of the situation and combine for a systematic campaign against the disease.

Practically significant facts about abortion disease, E. C. SCHROEDER and W. E. COTTON (*Amer. Jour. Vet. Med., 12 (1917), No. 2, pp. 73-78*).—A paper presented at the meeting of the U. S. Live Stock Sanitary Association held at Chicago in December, 1916, in which the authors present the practical results of investigations substantially as noted above.

Possibilities and limitations in control of abortion, C. J. MARSHALL (*Amer. Jour. Vet. Med., 12 (1917), No. 3, pp. 157, 158*).—A paper presented at the meeting of the U. S. Live Stock Sanitary Association at Chicago in December, 1916.

Investigations into the occurrence of onchocerciasis in cattle and associated animals in countries other than Australia, GEORGINA SWEET (*Proc.*

*Roy. Soc. Victoria, n. ser., 28 (1915), No. 1, pp. 1-51, pls. 5*).—Previously noted from another source (*E. S. R.*, 34, p. 582).

**Serum studies on hog cholera** (*Wisconsin Sta. Bul. 275 (1917), p. 41*).—The use of sodium iodoxybenzoate to increase the production of antibodies in immune sera, as reported by earlier investigators, was tested in the production of hog-cholera serum. While the serum of hyperimmunized animals so treated showed a slight increase in potency, the increase was not deemed "sufficient to justify the use of this agent in commercial manufacture."

[**Hog cholera inoculations with serum globulin**], F. C. MINKLER (*New Jersey Stas. Rpt. 1915, pp. 76-85*).—The results of the treatment of 201 animals (ranging in age from suckling to mature breeding animals five years of age) by the serum alone treatment with serum globulin are reported. Each animal was inoculated with 30 cc. of the globulin. Thirty-eight animals of the total number died, 31 of which had a temperature above 105° F. at the time of injection. All of the control animals not inoculated with serum, with the exception of two, died subsequently to being turned out to produce contact exposure with well animals.

Three cases of abortion followed the injection, one of which was undoubtedly due to injury received at the time of injection. Serum when injected into pigs whose temperature was normal at the time of inoculation protected in all cases. It is, however, considered not to have established any curative properties of economic worth.

**Special report on diseases of the horse** (*U. S. Dept. Agr., Bur. Anim. Indus., 1916, rev. ed., pp. 629, pls. 42, figs. 18*).—A revised edition of the work previously noted (*E. S. R.*, 15, p. 619).

[**Poultry disease observations**], H. R. LEWIS and W. C. THOMPSON (*New Jersey Stas. Rpt. 1915, pp. 120-122*).—Investigations made of the occurrence during the hot summer months of what was termed "summer poisoning" led to the conclusion that this trouble was a form of ptomaine poisoning resulting from the fowls eating decayed flesh of carcasses of other fowls. The only treatment found practical in such cases was the administration of a dose of Epsom salts, one-half teaspoonful dissolved in a little warm water and poured down the throat of each fowl.

**Campaign to eliminate bacillary white diarrhea** (*Massachusetts Sta. Circ. 65 (1916), folio*).—A revision of Circular 56, previously noted (*E. S. R.*, 34, p. 189).

**An intradermal test for Bacterium pullorum infection in fowls**, A. R. WARD and B. A. GALLAGHER (*U. S. Dept. Agr. Bul. 517 (1917), pp. 15*).—In searching for an accurate method of detecting the presence of the causative organism of bacillary white diarrhea in fowls that is simpler and cheaper than the agglutination test, the authors have found the intradermal test to give encouraging results.

In their experiments a killed culture of *B. pullorum* grown for about a month and held for several weeks before use and without further treatment than carbolizing has given the most satisfactory results. The edematous swelling resulting from the injection of this product into the wattle of a fowl, when observed at the proper time interval, is an indication of the presence of infection of *B. pullorum* in the fowl. Readings made at various time intervals have led to the conclusion that the 24-hour interval gives the most accurate results.

"The weight of evidence indicates that any perceptible swelling of the wattle should be regarded as significant. A second intradermal test made at an interval of four days gave results varying but little from the first test. Others made at intervals up to two months gave less accurate results the second time. Thus, there is no advantage in retesting.

"Of birds artificially infected with the disease and tested in the laboratory, in round numbers 90 per cent gave positive reactions; and in 6 per cent the test failed to indicate a reaction when lesions were present. In 3 per cent no reaction occurred and no lesions were present. In a field test on 231 birds made simultaneously with the agglutination test, the intradermal test at 38 hours failed to detect one case reported positive to the other test. In a second flock of 50 birds in which the two tests were compared, the intradermal test when read at 46 hours failed to indicate one case that was detected by the agglutination test. Another group of about 100 birds tested under unfavorable conditions gave less satisfactory results. . . . Autopsy does not furnish an absolute standard for comparing the accuracy of tests. Seventy-two per cent only of naturally infected birds that had reacted to one or both tests were found on autopsy to be unmistakably infected. . . .

"The intradermal test has already shown sufficient promise to warrant further extensive trials in the field in comparison with the agglutination test."

**Poultry farm disinfection, J. B. PAIGE** (*Massachusetts Sta. Circ. 66 (1916), pp. 4*).—This circular describes briefly some simple methods of disinfection applicable to the poultry farm.

**American records of Diocotophyme renale, M. C. HALL** (*Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 370, 371*).—The author calls attention to two records of the occurrence of the giant kidney worm additional to those compiled by Riley (E. S. R., 36, p. 86).

## RURAL ENGINEERING.

**Thirteenth biennial report of the state engineer of Wyoming, 1915-16, J. B. TRUE** (*Bien. Rpt. State Engin. Wyo., 13 (1915-16), pp. 379, pls. 11*).—A report for the years 1915 and 1916.

**Second report on the water powers of Alabama, B. M. HALL and M. R. HALL** (*Geol. Survey Ala. Bul. 17 (1916), pp. 448, pls. 19, figs. 4*).—This report gives the results of measurements of flow made on the important streams of Alabama.

**Surface water supply of the lower Mississippi River basin, 1915 (U. S. Geol. Survey, Water-Supply Paper 407 (1917), pp. 5-43+XXXIII, pls. 2)**.—This report, prepared in cooperation with the States of Colorado and New Mexico, presents the results of measurements of flow made on the Arkansas and Red River basins during 1915. A section on stream-gaging stations and publications relating to water resources is appended.

**Ground water for irrigation in the Morgan Hill area, California, W. O. CLARK** (*U. S. Geol. Survey, Water-Supply Paper 400-E (1917), pp. 61-108, pls. 3, figs. 5*).—This report deals with the geology and ground water of an area of about 15,730 acres in the Santa Clara Valley, Cal. Precipitation and stream flow data affecting the area are also included.

"The soils of the region range from gravelly clay loam to a rather heavy sandy loam and vary widely in fertility. In the central part of the area, about Morgan Hill, they consist predominantly of coarse, angular gravel and on the whole are the least fertile in the area, though even in this locality they show rather wide variations in character and fertility, some of them being very open and porous and others comparatively tight and impervious."

"In the Morgan Hill area the ground water occurs in the valley alluvium. Over most of the valley area the water table . . . lies at a depth of about 20 to 80 ft. below the surface of the ground during the low-water season and about 15 to 50 ft. during the high-water season. . . . Although the development of the ground water within the proposed irrigation district has been very slight, so far as it goes it seems to show satisfactory results, and apparently wells in this

area might be expected to yield enough water for irrigation. . . . It appears probable that as much as . . . approximately 1 acre-foot per acre will be annually available for irrigation within the district."

Pumping tests on three wells in the area and tables of logs of wells in the area are included.

Critical judgment and use of the waters of the pampas, F. A. MAZZA (*An. Soc. Cient. Argentina*, 81 (1916), Nos. 1-2, pp. 71-128, pls. 8, figs. 6; 3-4, pp. 129-213, fig. 1).—This report deals in general with the geology and soils of the pampas and the relation of soil and water, gives chemical analyses of both soils and waters, and discusses the waters with reference to their use for domestic purposes and irrigation and in the industries.

The waters are divided into two types, those low in mineral content and those highly mineralized. In general they are more alkaline than hard, but in the highly mineralized waters the hardness is greater than the alkalinity. The waters of low mineral content are said to contain very little sulphates and chlorids, but are relatively rich in bicarbonates, while the highly mineralized waters contain an abundance of chlorids and sulphates. The waters of low mineral content are considered suitable for drinking, irrigation, and boiler use, while the highly mineralized waters are said to be not fit for such uses.

The divining rod: A history of water witching, A. J. ELLIS (*U. S. Geol. Survey, Water-Supply Paper 416* (1917), pp. 59, figs. 4).—This is an outline of the history of the use of the divining rod for locating underground water supplies and of so-called water witching, and includes an introductory note by O. E. Meinzer and an extensive bibliography of works bearing on the subject.

"The outline of the history of the subject presented will probably enable most honest inquirers to appreciate the practical uselessness of 'water witching' and other applications of the divining rod. . . . It is difficult to see how for practical purposes the entire matter could be more thoroughly discredited."

The advice is given to all inquirers "not to expend any money for the services of any 'water witch' or for the use or purchase of any machine or instrument devised for locating underground water or other minerals."

Irrigation module investigations, 1913 (*Glav. Uprav. Zemleustr. i Zemled., Gidrom. Chast [Pub.]*, 1914, Nos. 1, pp. XII+387+49, pls. 17, figs. 18; 2, pp. XIX+391+344, pls. 79, figs. 44; 3, pp. VII+460+II, pls. 19, figs. 30; 4, pp. [III]+49; 1915, No. 5, pp. [III]+39, pls. 11).—This report is in four volumes and deals with duty of water investigations in Turkestan in 1913.

The soils of the regions studied consist mainly of fine-grained loess, sand, coarse dust, dust, silt, and fine particles. Experiments with alfalfa, cotton, winter wheat, and corn showed that for alfalfa the module is 0.36 second-liters per dessyatina (0.035 second-gallons per acre) for cotton 0.31 second-liters, for wheat 0.25 second-liters, and for corn 0.38 second-liters. Experiments on flooding and furrow irrigation are also reported.

It was found that a single irrigation of more than 128 cubic sageses per dessyatina (a depth of about 4.5 in.) checks the growth of cotton temporarily. An irrigation of 910 cubic sageses for the season giving not more than 227 cubic sageses at each irrigation increased the height of cotton but delayed its ripening. The irrigation of cotton during blooming delayed its ripening at the rate of three days per each 100 cubic sageses. The most profitable application of water to cotton proved to be 384 cubic sageses per dessyatina per season, divided into three to four irrigations.

A better yield of cotton was obtained with check irrigation than with flood irrigation of cotton planted broadcast. The yield of cotton was also increased by watering the soil previous to planting. The best interval between irrigation in check irrigation of cotton was about two weeks and in flood irrigation two

to three weeks. When the soil was not watered before planting the best yields of cotton were obtained with one irrigation before blooming and with three during flowering.

The apparatus used for distribution of irrigation water at the Karayaz experiment station is described, and a large amount of statistical and other data on climate, crop yields, and methods and amounts of irrigation are also included.

Spray irrigation, M. B. WILLIAMS (*U. S. Dept. Agr. Bul. 495 (1917), pp. 40, figs. 19*).—"The object of this bulletin is to familiarize the farmer with conditions under which spray irrigation may be undertaken profitably, suggest possible water supplies, and illustrate typical pumping machinery and distribution systems so as to aid the prospective irrigator in determining whether spray irrigation should have a place in his farm operations. It is also intended to present information necessary in working out an intelligent design and installation of a spray system."

With reference to economic conditions justifying spray irrigation it is stated that, assuming a cost of \$250 per acre on a stationary plant for a small acreage, the farmer should be able to increase his annual returns from each acre somewhat more than \$51. Adequate markets, labor, and fertilizer facilities are other essentials for successful spray irrigation, as well as good roads and equipment for quick hauling of perishable truck and berry crops.

With reference to farm conditions adapted to spray irrigation, it is stated that "spray irrigation can be practiced to advantage on both light and heavy soils. By this method it is possible to apply evenly to sandy soils the small quantities of water which such soils will retain, without the loss of water by percolation which might occur with other methods. It is possible also to apply to heavy clay soils the small quantities of water required to soften such soils when they have baked after rains and to apply water no faster than the soil can absorb it, thus preventing loss by surface run-off. Lands to be irrigated should be drained as completely as possible of excess moisture. Many tile-drained fields are the most responsive to crops under spray irrigation. Spray irrigation is practically independent of the topography of the field and can be applied to land too rolling or rough for surface methods. It is, therefore, adaptable to the irrigation of sidehills on which soils tend to wash or erode. . . .

"For spray irrigation sufficient water to cover the land to a depth of 1 in. per week for humid regions and 1½ in. per week for arid regions is believed to be a safe estimate for designing purposes. A spray plant should be large enough to supply these amounts of water in a reasonable length of time. This is accomplished generally by installing the system to spray from one-fifth to one-half of the total acreage at one time, depending somewhat upon the type of distribution used and the available water supply. . . .

"Three types of spray irrigation construction have been adopted more or less widely for field irrigation—(1) hose and movable nozzle or movable lines fed from an underground pipe system and hydrant, (2) circular nozzles fed from an underground pipe system, and (3) overhead spray lines fed from an underground main feed pipe. . . . The hose and portable nozzle system of spray irrigation is the oldest and least efficient of spray methods. It is impossible to get an even application over the entire field or under one position of the nozzle. The constant attendance necessary and the liability of over or under irrigation makes the cost of operation high and the results dependent upon the skill of the laborer. The greatest field for this type of irrigation seems

to be indoor spraying, outdoor sod lands, seed beds, and small garden plats. The first cost is the smallest of any type of spray irrigation."

Tests of irrigation pumping plants, F. C. PIATT (*Jour. Electricity*, 38 (1917), No. 3, pp. 79-82).—Efficiency tests on about 350 small irrigation pumping plants are reported. About 90 per cent of these plants consisted of small centrifugal pumps either direct or belt connected to electric motors. The results are summarized in the following table:

Results of tests of irrigation pumping plants.

Kind of pump.	Size of pump.	Number of tests.	Mean discharge per minute.	Mean suction lift.	Mean total lift.	Revolutions per minute of pump.	Mean input.	Mean over-all efficiency.	Mean estimated efficiency of pump.

The draining of orchard land, J. M. WARD (*Agr. and Stock Dept. Tasmania, Bul. 65 (1916), pp. 8, figs. 7*).—Brief general information on the subject is given.

[Iowa] laws relating to drainage, 1916, compiled by LOLA S. ELLIOTT (*Des Moines, Iowa: State, 1916, pp. 92*).—This publication compiled under the direction of W. S. Allen, contains the text of the law.

[Analyses of water samples, 1916], L. HELMBURGER (*Fla. Quart. Bul. Dept. Agr., 27 (1917), No. 1, pp. 173-175*).—Analyses of 16 samples of underground waters from different parts of Florida are reported.

Drinking water, A. T. CHARRON (*Rpt. Min. Agr. Prov. Quebec, 1916, pp. 113-115*).—Analyses of five samples of Quebec waters are reported and discussed. A sample of drainage water from a cheese factory which had been submitted to septic tank treatment showed "that the purifying supposed to be done in the septic tank was far from being perfect."

Nitrites in potable water, A. A. BADO and V. J. BERNAOLA (*An. Soc. Quim. Argentina*, 4 (1916), No. 15, pp. 251-255).—The works of others bearing on the subject are briefly reviewed, and it is concluded in view of the results obtained by the authors that the importance of the presence of nitrites in drinking water is exaggerated. It is considered more important to determine the source of the nitrites, if any exist.

Purification of drinking water with calcium hypochlorite, A. A. BADO and L. DASSO (*An. Soc. Quim. Argentina*, 4 (1916), No. 15, pp. 242-250).—The work of others bearing on the subject is reviewed and experiments on the purifying action of calcium hypochlorite on polluted river water are reported.

A 10 per cent solution of calcium hypochlorite containing 16 per cent of active chlorin was used. This was added to the water at rates of 0.05, 0.1, and 0.15 cc. per 1,000 cc. of water. Bacteriological examinations were made one, two, and five hours after treatment. Better results were obtained with this treatment from the bacteriological point of view than previous experimenters had obtained with a treatment with 0.015 gm. of calcium hypochlorite containing 35 per cent of active chlorin. The coli bacilli disappeared completely and the numbers of other objectionable organisms, which were numerous in the raw water, were reduced until almost negligible.

Further experiments in which 1, 2, and 3 cc. of calcium hypochlorite solution were used and examinations made after one, three, six, and nine hours showed that the diminution in numbers of objectionable organisms as related to that of the previous experiments was less in proportion to the amount of hypochlorite used. Experiments on the effect of calcium hypochlorite and aluminum sulphate when used together are also reported.

The results as a whole are taken to indicate that calcium hypochlorite is very effective in the destruction of coli, Eberth, and pyocyanous bacilli, and that small doses diminish the vitality of these organisms. In cases requiring a relatively high active chlorin content (33 per cent) and a relatively short time of contact appreciable results have also been obtained. *Bacillus subtilis* was found to be more resistant to this action.

Sixth biennial report of the state highway commissioner of Washington, Oct. 1, 1914, to Sept. 30, 1916, J. ALLEN (*Bienn. Rpt. State Highway Comr. Wash.*, 6 (1915-16), pp. 123, pls. 6).—The work and expenditures of the Washington state highway commission for this period are dealt with.

Third annual report of the country roads board of Victoria (*Ann. Rpt. Country Roads Bd. Victoria*, 3 (1916), pp. 70, figs. 20).—This is the third annual report of the board, dealing with permanent works completed and in progress, road-making machinery, motor-car registrations, investigations, and finances.

Regulations respecting highways, 1916, W. A. McLEAN (*Ontario Dept. Pub. Highways Ann. Rpt.*, 1916, App., pp. 11).—The text of the regulations is given.

Road construction for township road superintendents and overseers, W. A. McLEAN (*Ontario Dept. Pub. Highways Ann. Rpt.*, 1916, App., pp. 12, figs. 4).—This is a brief manual of instructions as to the essential features and considerations in the construction of the ordinary country roads.

County roads, F. G. MACDIARMID (*Ontario Dept. Pub. Highways Ann. Rpt.*, 1916, App., pp. 7).—The general features of the organization and construction of a county road system under Canadian highway improvement laws are briefly outlined.

Helpful suggestions for surveying country highways, S. P. BAIRD (*Engin. News*, 77 (1917), No. 5, pp. 180-182, figs. 3).—Some suggestions on special survey methods and devices from the practice of an experienced surveyor are given.

A step toward the rational design of concrete pavements, S. T. MORSE (*Engin. and Contract.*, 47 (1917), No. 6, pp. 135-137, figs. 4).—The causes of cracking in concrete pavements are discussed and a summary is given of experience tending to develop the design of concrete pavements, special mention being made of the work of the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture.

The fundamental principle of concrete road design is considered to be that the central thickness should be made to depend primarily upon the width. The data summarized are taken to indicate that a concrete pavement to remain uncracked must have a thickness equal to at least 4.5 per cent of its width. On this basis the author suggests that the formula for design of concrete roads

be modified in the following form:  $d = \frac{2.25B^2}{f} + \sqrt{\frac{P}{1.5f} + \frac{5B^4}{f^2}}$ . In this formula  $d$  = the thickness in inches,  $B$  = the breadth of the slab in feet,  $P$  = the concentrated load in pounds, assumed as 8,000, and  $f$  = the tensile stress in pounds per square inch in extreme fiber of concrete.

It is the author's purpose in this formula to indicate "that the minimum thickness should be not less than 5 in. Therefore, at the edges the pavement may be made 5 in. in thickness and be increased in thickness toward the center of the slab, as required by the formula." In comparison with current practice it is further pointed out "that narrow pavements are usually given a greater thickness than safety and economy require, and that wide pavements are usually given an insufficient thickness and hence are likely to crack longitudinally."

Possibilities of rural business from transmission lines, W. H. BURTIS and F. D. PAINE (*Proc. Iowa Sect. Nat. Elect. Light Assoc.*, 16 (1916), pp. 155-165, 168-170; *abs. in Elect. World*, 68 (1916), No. 5, pp. 221, 222).—It is the purpose of this paper to consider in a general way some of the questions relating to rural electric power business from transmission lines in Iowa and adjoining States.

It was found that of the 250 electric light and power companies in Iowa 60 are giving rural service. Of 52 companies reporting, the maximum number of rural customers per company is 80 and the minimum is 1. Twenty of the 52 companies give rural service to 179 customers from lines having voltages of 6,600 or above, of whom "17 companies serve 155 customers from their high-tension lines built to other towns, stepping the voltage down directly to 110-220. Ten of these companies use a high-tension voltage of 6,600 and serve 98 customers, the remaining seven use a high-tension voltage of 13,200 and serve 57 customers. Four companies serve 30 customers from their high-tension lines to other towns, first stepping the voltage down to 2,300 volts for distribution. The investigation shows only two companies have built lines to serve only farmers. These companies are using a voltage of 6,600 and serve only 10 or 12 customers."

"The highest voltage used on lines from which farmers obtain service is 33,000. This company gives service to 18 customers by first stepping the voltage down to 2,300 volts for distribution. . . ."

With reference to rates it was found that of 27 companies reporting, "all but two have the same charge per kilowatt-hour for rural service as for city service, and these two sell the energy at a lower rate per kilowatt-hour. . . . Seventeen of the 27 companies have the same minimum charge for rural service as for city service. Four of the remaining ten have a \$5 minimum; three have a \$3 minimum; and one a \$1.75 minimum. . . ."

"From experience obtained so far it is reasonable to conclude that it is not very profitable to install a number of isolated high-tension transformers upon

a main trunk line serving cities. The cost of interruptions to the service is likely to more than offset the possible profit from such business."

It is further concluded that "the farmer should pay for the rural service lines. These should be maintained and owned by the power company under its own franchise. The transformers and protective apparatus should preferably be furnished by the power company. The rate charged should be sufficient to cover the additional cost of giving such service."

**A gasoline tiller**, F. C. PERKINS (*Gas Engine*, 19 (1917), No. 2, pp. 61-65, figs. 5).—This article describes and illustrates a new attachment for moldboard plows, consisting of a toothed rotor in perpendicular juxtaposition with the moldboard of the plow. "This rotor is operated by a gasoline motor. The engine turns the rotors at high speed, the teeth of the rotor engaging the soil as it comes from the moldboard, and pulverizes or disintegrates the soil perfectly, throwing it out at the rear, thoroughly mixed with the sod, weeds, grass, manure, and any other form of surface growth or fertilizer which happens to be present, all forming a perfect seed and root bed."

**Farm buildings and building construction in South Africa**, W. S. H. CLEGHORNE (*New York and London: Longmans, Green & Co., 1916, pp. XXIII+325, pls. 5, figs. 218*).—This book, prepared for farmers, students, teachers, and agricultural engineers, with special reference to conditions in South Africa, deals with the general arrangement and design of farm buildings, building materials, details of construction, stables, sanitary dairy sheds, bull boxes and exercise yards, small butter making and cheese making dairies, piggeries, silos, a reservoir, cattle and sheep dipping tanks, sheep shearing sheds and yards, a small cottage, and a cool storage room, the protection of buildings from lightning and white ants, etc. An appendix is also included containing sections on the calculation of horizontal reinforcing bars (hoops) in the wall of the silo, a design of a reinforced concrete tank or reservoir, and the calculation of graduations showing the volume of liquid in a cattle dipping tank at various depths.

**The reconstruction of farm buildings in devastated areas**, R. DE SAINT-MAURICE (*Vie Agr. et Rurale*, 7 (1917), No. 1, pp. 9-17, figs. 8).—Methods of reconstruction of farm buildings in localities in France devastated by the war are described.

**Mechanics of the household**, E. S. KEENE (*[Agricultural College, N. Dak.: Author, 1911], pp. 234, figs. 211*).—This publication, prepared as a contribution to physics, contains the following chapters: The steam-heating plant, the hot-water heating plant, the hot-air furnace, temperature regulation, management of the heating plant, plumbing, water supply, sewage disposal, coal, atmospheric humidity, ventilation, lighting and heating with gasoline, acetylene gas machines, and gaseous and liquid fuels.

**Domestic water supply** (*Colo. Agr. Col. Ext. Serv. Bul., 1. ser., No. 108 (1916), pp. 11, figs. 5*).—This is a popular bulletin on the subject, in which five steps in the process of providing running water in the farmhouse are described. These vary from the cold water supply over a sink in the kitchen to a bathroom and hot and cold water supply outfit. The use of the windmill for pumping is also described. A feature at variance with accepted sanitary practice which is recommended is the so-called gravel waste pit, situated close to the house and well, and used for the disposal of waste water. It is stated that "the waste pit consists of a hole, say 3 ft. across and 5 to 6 ft. deep, which is filled with gravel. This can be near the house in nearly every case, because only wash water and similar waste waters will be run into this pit."

**House equipment for running water**, J. L. MOWRY (*Univ. Minn., Col. Agr., Ext. Bul. 61 (1916), pp. 8, figs. 12*).—This bulletin briefly describes gravity,

hydropneumatic, and pneumatic water systems and the hydraulic ram, and describes and illustrates fittings used in water supply and heating systems.

Privies and cesspools, C. G. WIGLEY and M. KNOWLTON (*Pub. Health News N. J.*, 2 (1916), No. 5, pp. 141-158, figs. 9).—This article deals with privies, cesspools, and leaching cesspools, and includes diagrammatic illustrations of different types of each.

Disposal of sewage in rural school districts, C. G. GILLESPIE and MARGARET S. McNAUGHT (*Cal. Bd. Ed. Bul.* 17 (1916), pp. 16, figs. 7).—This report deals in general with rural school sanitation and very briefly discusses sanitary privies and septic and Imhoff tank systems for rural school sewage disposal.

### RURAL ECONOMICS.

Land tenure in the United States with special reference to Illinois, C. L. STEWART (*Univ. Ill. Studies Soc. Sci.*, 5 (1916), No. 3, pp. 135, figs. 22).—The author discusses in general the situation regarding land tenure for the United States as a whole, and conditions in Illinois in detail. Among his conclusions are the following:

"It appears that the forms of tenure have been phases accompanying, limited by, and modifying the conditions and changes in the agricultural economy of the State. The prevalence, sectional character, and growth of farming by tenant operators is chiefly governed by the real value of the shares of the owners and tenants in the surplus of operation. Tenancy forms a sort of cumulative index of the effectiveness of the desire of the owners to escape the operation of their land, and of the ineffectiveness of the desire of tenants to become owners.

"Share tenancy has been more prevalent than cash tenancy, though cash tenancy predominates in the northern part of the State and has been more characteristic of tenants who were advanced in years and who were operating farms whose owners were resident at a considerable distance from their farms. . . .

"The farms of no single form of tenure can be held to be superior in all ways. Managed farms had the highest value in buildings and live stock per acre, and farms of owners were characterized by the highest value of implements and machinery per acre. In values of domestic animals the farms of tenants were below the average, when either the total value or the value per head is considered. The farms of tenants were largely devoted to the production of the money crops. This was particularly true of share tenant farms. Yields were superior in the case of farms operated by managers and by cash tenants. . . .

"It was shown by the age statistics that young operators were more generally characterized by tenancy, especially on the share basis, and that young owners were most heavily encumbered. Advancing years tended to replace share with cash tenancy, tenancy with ownership, and encumbrance with freedom from mortgage debt. The latest census data, however, indicate that an influence is at work restraining this movement. . . .

"Farming efficiency in the future will probably consist to a greater extent in the ability to increase net profits through cooperative dealing with the market. The efficiency test must, therefore, rule more strongly against operators of the tenures whose characteristics are opposed to successful cooperative effort on their part.

"It is not necessary, however, that the farmers of other tenures operate as efficiently as the owners themselves would operate. If owners prefer to have their land operated by others than themselves, and if their holdings are sufficiently large, they may content themselves with the financial disadvantage resulting from their refusal to operate their own land. . . .

"The test of productive efficiency may be somewhat slow in acting and costly but it bids fair in the long run to penalize unsound farming regardless of the tenure of the operators, and to guaranty, therefore, the survival of the best forms of tenure and of the best individual operators."

**Tenancy in the South**, F. A. MERRILL (*Bul. State Normal School [Athens, Ga.]*, 4 (1916), No. 1, pp. 14, fig. 1).—The author discusses in general the tenancy problem of the South and concludes with the following statement:

"To our tenants we are indebted for our wonderful agricultural productiveness and we must draw our farm leases in such a way that we may aid them in keeping their hard-earned pittance at home. We must evolve some leasing system that will protect our people and that will not place a premium upon the importation of the very necessities of life. The problem of the South has ceased to be one solely of production and has resolved itself into one of wealth retention."

An economic study of farming in Sumter County, Georgia, H. M. DIXON and H. W. HAWTHORNE (*U. S. Dept. Agr. Bul. 492 (1917)*, pp. 64, figs. 6).—The authors summarize the results of this study as follows:

"Farm profits on these farms for the year of the survey (1913) were in direct proportion both to the number of acres in crops and the yield of cotton per acre. On farms of approximately the same size labor incomes were high when the yield of cotton was high and low when the yield was low. On owner farms of approximately the same size labor incomes were high when the percentage of crop area in cotton was high, and vice versa. The white farmers of the area are getting a much higher yield per acre than the colored farmers.

"Cotton occupies 59 per cent of the tilled area of the farms surveyed, and [at 12 cts. per pound] returns 89 per cent of the total farm receipts. Corn occupies over one-fourth of the tilled area and was grown on every farm visited. Oats are the principal small-grain crop and are also used for hay and pasture. Cowpeas for hay and seed occupy about half as much land as corn. About 85 per cent of the land utilized for a second crop in 1913 was in cowpeas.

"The cost of producing cotton, computed for 534 farms, was found to average about 10.5 cents per pound of lint. The cost of producing cotton on these farms decreases with increase in size of farm. The relative rate of reduction in cost due to increase in acreage is greater for the farms ranging from small to medium than for those ranging from medium to large. The cost of producing cotton on these farms decreases with increase in yield per acre. The reduction due to increased yield is relatively greater for farms with yields ranging from low to medium than for farms with yields ranging from medium to high. On farms with high yields of cotton per acre the cost per acre was high, but the cost per pound low.

"Aside from work stock, hogs constitute the most important class of live stock. . . .

"In efficiency in utilizing labor, mules, and machinery the large farms have a great advantage over the small ones. On the small white-owner farm one mule works 10 acres of cotton and 11 acres of other crops, while on the large farm one mule works 19 acres of cotton and 10 acres of other crops."

**Farm management survey [of Monmouth County, New Jersey]**, F. APP (*New Jersey Stat. Rpt. 1915*, pp. 184-193, pl. 1).—These pages contain data obtained in the survey previously noted (*E. S. R.*, 36, p. 492). Attention is drawn to the large amount of capital required in this region to conduct a profitable farming business.

**The possible Wayne County farm**, C. E. THORNE (*Ohio Sta. Bul. 304 (1916)*, pp. 209-225, figs. 2).—The author has analyzed the results obtained from his

fertilizer experiments at Wooster to determine whether they could be profitably applied to other Wayne County farms. He concludes that it would pay the farmers to apply more fertilizers even if less land could thereby be cultivated, also to purchase a part of the fertilizers to be used by tenants.

The resources and opportunities of Montana, S. MAXWELL (*Helena, Mont.: State, 1916 ed., pp. 191, figs. 93*).—In this volume are described the agricultural, forest, and climatic conditions and the opportunities for further development and settlement in Montana.

How the Federal Farm Loan Act benefits the farmer, C. W. THOMPSON (*U. S. Dept. Agr., Farmers' Bul. 792 (1917), pp. 12*).—This points out the main provisions of the act (E. S. R., 35, p. 101) and shows how farmers can take advantage of it.

The Jewish agricultural and industrial aid society (*Jewish Agr. and Indus. Aid Soc. Ann. Rpt., 1915, pp. 61; 1916, pp. 60*).—In these two annual reports are discussed the activities of the society, the advancement of the agricultural interests of the Jewish race through the granting of loans, and the education and placing of Jewish laborers on farms.

Agricultural credit in France, A. SOUCHEN (*Évreux, France: C. Hérissey, 1917, pp. 70*).—In this publication, prepared for distribution at the Panama-Pacific International Exposition, the author has given a brief history of the laws relating to long and short term credit and their provisions. He has also included a model law for local and district agricultural credit associations. \*

Cotton as a world power, J. A. B. SCHERER (*New York: Frederick A. Stokes Co., 1916, pp. 10+452*).—The author traces the history of the use of cotton in the world's industry and its influence upon the social and economic life of the different nations.

Report on the storage and handling of wheat in bulk in South Australia (*Adelaide, So. Aust.: Govt., 1915, pp. 55, pls. 19, figs. 3*).—In this report some of the disadvantages of handling wheat in bags are pointed out. It is considered that the bulk system is better than the bag system because the excessive loss on bags to the farmer can be eliminated, wheat can be handled more quickly and cheaply between the farm and export wharf, more economical use of railway rolling stock will result, bulk elevators will save and provide more economical use of land area and wharf frontage at ports, and by reliable and disinterested government operated inspection the grading and weighing system will encourage the farmer to grow the best grades, and the financing will be done with less difficulty, more uniformity, and greater readiness.

There is also included a paper by James Spelman on the handling of grain in Canada.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt., 3 (1917), No. 2, pp. 13-20, fig. 1*).—This number contains the usual data as to the estimated farm value of important products and the range of prices of agricultural products at important centers. In addition there are given special data regarding the methods of gathering grain crops, the extent of winter oats grown in the Southern States, wool production in 1916, the trend of prices and yield per acre of crops, the estimated value of farm production in 1916, the proportions of the total corn crop consisting of white, yellow, and mixed varieties, the condition of truck crops in the Southern States, etc., and special articles on the sizes of the family and farming in Iowa County, Wis., and alsike clover growing.

[Agricultural statistics of Finland] (*Bidr. Finlands Off. Statist., III, Nos. 7 (1914), pp. 161; 8 (1915), pp. 145; 11 (1916), pp. 145*).—These volumes contain data regarding the yield of crops and number of domestic animals by government and minor subdivisions, operations of creameries, wages of agricultural laborers, and monthly prices of agricultural products.

Agricultural and live stock statistics of Finland (*Statist. Årsbok Finland, n. ser., 13 (1915), pp. 116-143*).—These pages continue the data previously noted (*E. S. R., 35, p. 497*).

Annual report of the department of agriculture, Uganda, 1916 (*Ann. Rpt. Dept. Agr. Uganda, 1916, pp. 62*).—This report continues information previously noted (*E. S. R., 34, p. 291*), adding data for the year ended March 31, 1916.

### AGRICULTURAL EDUCATION.

[The teaching of agriculture in high schools throughout the United States] (*Quart. Alpha Zeta, 14 (1916), No. 5, pp. 82, figs. 30*).—This issue is devoted to articles showing along what lines secondary agricultural education has been developed in the different States, especially with reference to method of organization of instruction, the school plant and the political area to be served by the different types of schools as follows: Agriculture in Alabama High Schools, by W. C. Blasingame; Agriculture in California High Schools, by W. G. Hummel; Agricultural Education in Indiana, by Z. M. Smith; Agricultural Education in Maryland, by J. E. Metzger; The Massachusetts Home-project Plan of Vocational Agricultural Education, by R. W. Stimson; Agriculture in the Secondary Schools of Michigan, by W. H. French; Agriculture in the Public High Schools of Minnesota, by A. V. Storm; Agriculture in Montana High Schools, by C. A. Bush; Agricultural Education in the State of New York, by L. S. Hawkins; Agriculture in the Secondary Schools of North Dakota, by W. A. Broyles; Agriculture in New Hampshire High Schools, by G. H. Whitcher; Vocational Agricultural Education in Pennsylvania, by L. H. Dennis; Development and Present Status of Agriculture in Secondary Schools of Texas, by J. D. Blackwell; Agricultural Education in the State of Vermont, by F. B. Jenks; Agriculture in the High School of Wisconsin, by H. N. Goddard; and Development of Special Agricultural Schools in the United States, by C. H. Lane.

Agricultural education in Argentina, W. DAWSON, JR. (*U. S. Dept. Com., Com. Rpts., No. 13 (1917), pp. 201-204*).—A brief review is given of the present status of agricultural education facilities in Argentina since the foundation of the first school of agriculture and stock raising at Santa Catalina on August 6, 1883. The instruction is classified as follows: (1) Higher—colleges of agriculture and veterinary science at the universities of Buenos Aires and La Plata; (2) that dependent on the Direction General of Agricultural Education, including four special schools for vine culture and wine making, agriculture and zootechnics, rural administrator, and agriculture and sugar making, respectively; seven practical schools of agriculture; 5 agronomic and 9 experiment stations, as well as 4 substations; district agronomists; and a farm school for women at Tandil, Buenos Aires; and (3) other miscellaneous national, provincial, and private institutions. The 1916 budget for the Direction General of Agricultural Education contained an appropriation of \$917,591, devoted almost exclusively to current expenses, salaries, etc. To encourage the maximum production in farm schools for educational and financial reasons the institutions are now authorized to distribute 50 per cent of the net profits among their staff and pupils, the remaining 50 per cent being devoted to improving the establishment.

[Agricultural and forestry instruction in Austria and Denmark], edited by R. MILTNER and E. VITAL (*Land u. Forstw. Unterrichts Ztg., 30 (1916), No. 1-2, pp. IV+114+LXII*).—In addition to several articles noted elsewhere, this issue contains an article on The Reform of the Final Examination at the Agricultural Intermediate Schools [in Austria], by E. Vital; statistics and organi-

zation lists of the faculties of the agricultural and forestry education institutions in Austria in 1915-16; and a review of agricultural literature.

**Agricultural instruction in Denmark**, S. R. VON RAMULT (*Land u. Forstw. Unterrichts Ztg.*, 30 (1916), No. 1-2, pp. 84-88).—This is an account of the present status of agricultural instruction in Denmark.

**Report of the department of agriculture of Norway for 1915** (*Aarsber. Offentl. Foranst. Landbr. Fremme, 1915, III, Statsforanst.*, pp. LX+819, pls. 3, figs. 82).—This is the annual report on the work of the various government agencies for the promotion of Norwegian agriculture, including chemical, seed, and milk control stations, experimental farms, sheep farms, dairy and horticultural schools, the school of home economics for training teachers, itinerant instructors, etc.

**Technical education in tropical agriculture** (*Trans. 3. Internat. Cong. Trop. Agr., 1914, vol. 1, pp. 1-56*).—These transactions include the papers in full on technical education in tropical agriculture, among others Agricultural Education in the Punjab, and A Note on Six Years' Experience in Teaching Agricultural Science in Northern India, by J. H. Barnes; and Agricultural Education in the Gold Coast, by W. H. Patterson.

**Education through farm demonstration**, B. KNAPP (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 67 (1916), No. 156, pp. 224-240).—The author traces briefly the origin and history of the development of the system of farm demonstration teaching through men and women county agents.

**The home demonstration work**, MARY E. CRESWELL (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 67 (1916), No. 156, pp. 241-249).—An account is given of the organization and development of the home demonstration work conducted in the 15 Southern States under cooperative agreement between the several state colleges of agriculture and the States Relations Service of this Department. A systematic 4-year program of work has been adopted.

**The junior home project work**, F. L. GRIFFIN (*Cornell Countryman*, 14 (1917), No. 4, pp. 283-286, figs. 2).—The author describes the junior home project work just being introduced into the rural and graded schools of the State of New York.

The work is organized and developed by the state department of education and is directed and supervised locally by the superintendents of schools. The New York State College of Agriculture is supplying the necessary directions and subject matter to the project students and their teachers. The projects—potato and corn growing, vegetable gardening, poultry raising, dairy herd record keeping, foods and clothing—may be undertaken by boys and girls in the seventh and eighth grades, or by those twelve years of age and over whether attending school or not.

A complete junior project consists of a definite amount of school study, at least 45 minutes a week or its equivalent, and supervised home work which must be visited at least three times during the season by the superintendent of schools or by some qualified person designated by him. A project notebook must be kept and a final report filed with the superintendent of schools. A pupil who successfully completes a junior home project and is recommended by the superintendent of schools will receive one regent's count toward high school graduation. An agricultural project requires a calendar year for its completion, and a pupil may receive only one credit each year for two years for doing junior project work.

**The organization of the school farm**, A. OSTERMAYER (*Land u. Forstw. Unterrichts Ztg.*, 30 (1916), No. 1-2, pp. 1-17).—The author discusses the functions of the school farm, i. e., instruction primarily, demonstration, and investigation.

In his opinion the school farm should be conducted as a model farm, but need not provide everything that is desirable, this resulting in what may be called a "museum farm" which is occasionally seen. One type of farming, adapted to local conditions, should be pursued, the variations in which to suit different local conditions can be explained in the theoretical instruction. The farm should be organized for profit and should be under the direction of the instructor in farm management and bookkeeping.

The extent of the farm practice should be confined to the aims of the instruction of the school with which it is connected. These aims should be to gain (1) manual skill in farm operations, (2) a survey of the individual branches of the farm, i. e., of soil and animal production, and (3) a survey of the whole farm—its organization and management, together with the fundamental reasons and conditions for success. These objects can be accomplished more thoroughly on a school farm than on a private farm. The methods of farm practice adapted to the farm schools and the agricultural intermediate schools in Austria are briefly discussed.

**School fairs** (*Agr. Gaz. Canada*, 4 (1917), No. 1, pp. 48-73, figs. 11).—This is a report for the past year on the progress of school fairs in the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Alberta, and British Columbia.

**Nature in farming**, J. W. PATERSON (*Melbourne, Aust.: Lothian Book Publishing Co., 1916, pp. XVI+221, figs. 137*).—This book, adapted for the use of schools and colleges and of the farmer as a source of reference, discusses scientific principles in their relation to farm practice, including plant growth, climate, soils, manures, drainage, irrigation, cereal, leguminous, root, and other crops, rotation of crops, insect enemies and fungus diseases, farm animals, feeds and feeding, wool and other fibers, milk and its products, and micro-organisms and decay.

**Field crops for the cotton-belt**, J. O. MORGAN (*New York: The Macmillan Co., 1917, pp. XXVI+456, figs. 75*).—This book presents the science and art of field crop production in the South and has been written primarily to meet the needs of the college student and also to be of service to the farmer and the general reader. It treats in considerable detail of cotton and corn, as regards classification, description, and physiology of plant, principal species, varieties, breeding, soils, climatic adaptations, fertilizers, manures and rotations, tillage, harvesting and marketing, and insect enemies and diseases. In less detail oats, wheat, rye, barley, rice, sorghums, sugar cane, and the peanut are similarly considered. Each crop is taken up separately.

**[Tree study]** (*Dacey Inst. Tree Surgery Instr. Book, 1914, No. 13, pp. 24, figs. 7; 1915, Nos. 14, pp. 23, figs. 11; 16, pp. 19, figs. 15; 17, pp. 19, figs. 21; 18, pp. 32, figs. 31; 19, pp. 23, figs. 19; 20, pp. 20, figs. 20; 21, pp. 24, figs. 26; 22, pp. 22, figs. 25*).—This series of lessons includes studies in landscape forestry, fruit growing, and tree surgery.

**The science and art of home making**, CARRIE A. LYFORD (*Ann. Amer. Acad. Polit. and Soc. Sci., 67 (1916), No. 156, pp. 40-46*).—The author briefly discusses the school in the study of home making, the home cottage or apartment as a laboratory, points of emphasis in the curriculum, the development of a unified curriculum, and the growth of the movement.

"To-day home economics is taught in all of our state agricultural colleges to which women are admitted; in practically all of our state normal schools, and in more than 3,000 high and grade schools. It has become a popular course in private schools but is not yet included in the curricula of the leading women's colleges. Correspondence courses of collegiate grade are carried on by four

state institutions. In four states—Louisiana, Oklahoma, Iowa, and Indiana—the teaching of home economics in all public schools is required by law. In many of the normal schools brief courses are required of all women students to give them a broader perspective for their general teaching, to enable them to introduce courses in the rural schools, and to prepare them for housekeeping. State supervisors of home economics have been appointed in four States. Eleven other States have some special system of home economics supervision. Twenty-three States have prepared courses of study in home economics for the common schools. . . .

“The funds made available by the Smith-Lever Act have led to a great increase in the amount of extension teaching in the rural districts. Women’s clubs and other organizations are furthering the study of homemaking in towns and cities. The public press recognizes the movement as of universal interest.”

### MISCELLANEOUS.

**Annual report of the director for the fiscal year ending June 30, 1916** (*Delaware Sta. Bul. 116 (1917), pp. 31*).—This contains the organization list and the report of the director on the work and publications of the station. It includes a financial statement for the fiscal year ended June 30, 1916, as well as a report of the extension service.

**Annual Report of New Jersey Stations, 1915** (*New Jersey Stas. Rpt. 1915, pp. XXVIII+39 $\frac{1}{4}$ , pls. 55*).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1915, and for the College Station for the fiscal year ended June 30, 1915, a report by the director and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. Reports of the fertilizer inspections have been noted in Bulletins 285 (E. S. R., 34, p. 625) and 287 (E. S. R., 35, p. 128), and feeding stuffs in Bulletin 283 (E. S. R., 34, p. 665).

**Report of the director for 1916, J. G. LIPMAN** (*New Jersey Stas. Bul. 298 (1916), pp. 51*).—This contains the organization list and a report of the director on the work and publications of the station during the year. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**County experiment farms in Ohio, 1915** (*Ohio Sta. Bul. 303 (1916), pp. 207, figs. 28*).—Reports on the Miami, Paulding, Clermont, Hamilton, Washington, Hancock, Trumbull, and Mahoning county experiment farms for 1915 are given. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**The work of the experiment station and agricultural extension service for 1916** (*Wisconsin Sta. Bul. 275 (1917), pp. 92, figs. 41*).—Part 1 of this report, by H. L. Russell and F. B. Morrison, deals with the work of the station, the experimental features not previously reported being abstracted elsewhere in this issue. Part 2, Carrying Agricultural Science to the Farm, by H. L. Russell and K. L. Hatch, reports on the extension activities. Part 3 contains brief summaries of the station publications of the year, and part 4, a financial statement as to the federal funds for the fiscal year ended June 30, 1916.

**The Department of Agriculture of the Union of South Africa: A short account of its history, organization, and activities** (*Pretoria: Govt., 1915, pp. 32*).

**Manual of agricultural laws, compiled and edited by R. E. ANNIN** (*Boston: State Bd. Agr., 1916, pp. 195*).—A compilation of the Massachusetts laws dealing with agriculture as they stood at the prorogation of the legislature in 1916.

## NOTES.

---

**Connecticut State Station.**—Waldo L. Adams has been appointed chemist, beginning May 1.

**Montana College.**—A law passed by the last legislature appropriated \$10,000 for the reimbursement of the cost of transportation to and from their homes of students at the college, the state university, the state school of mines, and the state normal college. Expenditures not exceeding \$5 are excepted. The purpose of the act is to equalize the cost of attendance at these institutions to students coming from distant parts of the State.

**New Mexico College and Station.**—Cleave W. Humble, a 1917 graduate of the college, has been appointed assistant agronomist, vice J. G. Hamilton, whose resignation has been previously noted.

**North Dakota College.**—A school of education has been organized with four courses covering four years and two courses covering two years for completion. The four-year curricula are designed for teachers of agriculture, the mechanic arts, science, and vocational and rural school administration, while the two-year curricula are for teachers in consolidated schools and special teachers. Arland D. Weeks, professor of education, has been appointed dean of the new school.

**Ohio State University.**—The first class of three-year students in the College of Agriculture was graduated March 16. The class numbered 62, of whom 52 will return to the farm, 5 will take up market gardening, and 5 cow testing association work. The total enrollment in this course is now 225, which is somewhat smaller than was anticipated.

Wm. L. Clevenger, instructor in dairying, has resigned to accept a position with the Dairy Division of the U. S. Department of Agriculture, in connection with its demonstration work in dairy manufactures in Tennessee and North Carolina.

**South Carolina College and Station.**—Dr. F. H. H. Calhoun has been appointed director of resident teaching. C. C. Newman, professor of horticulture and horticulturist, has been put in charge of the college farm. This farm comprises about 600 acres and is used in growing food for the students and feed and pasture for the live stock at the institution.

**Texas College.**—The junior agricultural college, established by the last legislature as previously noted (E. S. R., 36, p. 599), has been located at Stephenville, about 100 miles southwest of Fort Worth. The buildings and grounds of the John Tarleton College have been acquired for the purpose, and the citizens of Stephenville and Erath County have donated 500 acres of land additional, to be used for experimental and demonstration work in connection with the institution. They have also subscribed \$25,000 for a student loan fund.

A second junior college has been established at Arlington, between Fort Worth and Dallas. The property of a small military academy has been transferred to the State, and efforts are under way to secure local contributions for additional aid and a student loan fund.

Provision has been made for a state educational survey by a board consisting of the presidents of the state university, the A. & M. College, the College of Industrial Arts, and one of the state normal schools, the state superintendent of public instruction, and the state commissioner of agriculture. A report is to be submitted to the next legislature. An appropriation of \$2,000,000 was also granted by the legislature for the benefit of the rural schools.

**Agricultural Education and Research in Latin America.**—*School and Society* announces that a Pan-American university has been established in the Republic of Panama. The trustees are to consist of the Secretary of Public Instruction of Panama and the diplomatic representatives of the American Republics or their delegates, together with similar representatives of other nations which may maintain chairs in the university. It is hoped that the institution may be of international value, especially along the lines of medicine, law, and agriculture.

In Venezuela, a presidential decree of March 12, 1917, creates an experimental station of agriculture and forestry, with an acclimatization garden, to be located near Caracas, and intended to serve as a model for other such stations to be established in other parts of the Republic. The objects of the station are the improvement of the methods of cultivation of the principal agricultural products of the country; the introduction, selection, and distribution of seeds; experiments in reforestation; the suitability of soils to crops and of crops to the various regions; and practical work for the training of agricultural foremen and forest rangers. H. Pittier, until recently with the U. S. Department of Agriculture, has been appointed in charge of the station and will also superintend the making of a survey of the unoccupied land of the Republic, which has recently been ordered.

The Council of Public Instruction of Ecuador has arranged to establish an agricultural class connected with the faculty of science of Central University at Quito. The professor in charge of this course is also to edit an official bulletin to encourage the study of agriculture.

**Organization of Agricultural Work in Java.**—Agricultural work in Java is mainly organized under the Department of Agriculture, Industry, and Commerce, for which appropriations of about \$3,000,000 per annum are available. The agricultural work consists of 14 main bureaus besides several experiment stations. Two of these, the experiment station for tea culture at Buitenzorg and for tobacco at Klaten are in close relation with the department, although supported in part by planters or their associations. Less closely related to the department, but receiving some of its funds, are the station at Salatiga, devoted to local work on coffee, cacao, etc.; that at Malang, occupied chiefly with coffee and rubber; and that at Djember, principally devoted to tobacco and rubber. There are also two stations without official relations, the sugar-cane station at Passeroean with its six substations, and the Deli tobacco station at Medan, Sumatra. Efforts are taken, however, not to duplicate these activities.

Some of the principal enterprises within the department are the bureau of forestry, the botanic gardens, the institute for phytopathology and plant breeding, an office of agrogeology and agricultural chemistry, the veterinary institute and service, a laboratory of microbiology, and special work with rubber, coffee, and cinchona.

# INDEX OF SUBJECTS.

NOTE.—The abbreviations "Ala. College," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective State experiment stations; "Alaska," "Guam," "Hawaii," and "P. R." to those of the experiment stations in Alaska, Guam, Hawaii, and Porto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

	Page.		Page.
Abacá—		Acorns, germinating.....	242
culture experiments.....	229	Acridiidae injurious in north Georgia.....	252
fiber, anatomy of.....	229	<i>Acrocystis batata</i> , studies, Del.....	544
standard grades.....	634	<i>Actinomyces scabies</i> , studies.....	847
Abattoirs. (See Slaughterhouses.)		Actinomycetes—	
<i>Abbotana clemataria</i> , studies, Mass.....	54	as affected by inorganic salts.....	526
Abderhalden reaction, studies.....	380, 381	function in soils.....	518
<i>Ablerus</i> —		<i>Actinonema rosæ</i> —	
<i>clisiocampæ</i> , notes.....	556	notes.....	348
<i>perspectosus</i> n.sp., description.....	259	treatment, Can.....	453
Abortion—		Adams Act, decade of work under.....	301
contagious, control in England.....	275	<i>Æcidium</i> spp., telial stages.....	245
contagious, dissemination.....	277	Aedes, new, of California.....	552
contagious, in Canada.....	179	Aerological station, Drexel, U.S.D.A.....	419
contagious, in cattle.....	82	African coast fever, blood observations in....	479
383, 675, 676, 680, 881, 882, 883		Agar—	
contagious, in cattle, U.S.D.A.....	883	for bacteriological use.....	131
contagious, in cattle, immunity.....	481	nutritive value and use.....	864
contagious, transmission by milk.....	480	sources, preparation, and composition...	716
infectious, in cattle, Ind.....	777	Aggregates, nonhomogeneous, specific gravity	683
infectious, in mares, Ky.....	780	Agricultural—	
infectious, in swine.....	483	and mechanical society of South Carolina,	
Abseission in plants.....	225	history.....	688
Absorbents, effect on soils.....	214	arithmetic, textbook.....	597
Absorption, review of investigations.....	622	bank of Philippines.....	689
Acacia—		chemistry. (See Chemistry.)	
descriptive notes.....	45	clubs, decline in Oklahoma.....	94
of Australia, description.....	844	colleges, laws concerning, U.S.D.A.....	598
Acetaldehyde in grape must.....	801	colleges, organization lists, U.S.D.A.....	794
Acetic acid—		colleges, treatise.....	791
effect on calcium phosphate.....	712	colleges, work and expenditures, U.S.D.A.	794
effect on hemolytic reaction.....	878	(See also Alabama, Arizona, etc.)	
rôle in digestion.....	763	cooperation in Bengal.....	593
Acetone, effect on hemolytic reaction.....	878	cooperation in Bihar and Orissa.....	290, 689
<i>Achorutes armatum</i> , remedies, N.J.....	854	cooperation in Denmark.....	392
Achrysocharellidae, occurrence in North		cooperation in United States.....	689
America.....	557	cooperation in Vermont.....	92
Acid phosphate. (See Superphosphate.)		credit in Ajmer-Merwara.....	392
Acidimetry, indicator for.....	13	credit in British India and Dutch East	
Acidosis, effect on creatin elimination.....	161	Indies.....	493
Acids—		credit in California.....	593
absorption by plant tissue.....	433	credit in France.....	594
amino. (See Amino acids.)		credit in North Carolina.....	289
effect on germination of seeds.....	29	credit in Tuscany.....	392
effect on lime requirement of soils, Mich..	210	credit in United States.....	289, 688, 689, 894
fatty, determination.....	673	credit in United States, U.S.D.A.....	894
localization in fleshy fruits.....	110	development in northern Ontario.....	697
mineral, action on natural phosphate rock		economics. (See Rural economics.)	
organic, action on pepsin.....	711	education—	
rôle in digestion.....	763	boys' and girls' club work in.....	297
volatile, determination in wine.....	112	for women.....	793
volatile fatty, determination.....	506	in Argentina.....	895

Agricultural—Continued.	Page.	Agricultural—Continued.	Page.
education—continued,		Organization Society, report.....	392
in Canada.....	793	phosphate. (See Phosphate, insoluble.)	
in China.....	799	production and trade in Great Britain	
in Gold Coast.....	896	and Ireland.....	291
in Great Britain.....	595, 798	production in Austria.....	291
in India.....	806	products, marketing.....	91, 392
in Massachusetts.....	93	products, marketing in western Canada..	493
in New South Wales.....	292	products, prices in Canada.....	593
in Nova Scotia.....	193	products, valuation on dry matter con-	
in Philippines.....	495	tent, U.S.D.A.....	92
in Saskatchewan.....	291	reeducation of soldiers.....	794
in Scotland.....	394	research and experiment.....	5
in Victoria.....	292	research in Canada.....	793
in Wales.....	495	research in Great Britain.....	798
institutions in Sweden.....	690	research in Scotland.....	394
purpose.....	193	resources and opportunities in Vermont..	290
vocational, in United States.....	701	resources of Georgia.....	790
(See also Agricultural instruction.)		resources of Montana.....	894
engineering, bibliography.....	400	resources of Rhode Island.....	93
experiment stations. (See Experiment		schools, drawing for, U.S.D.A.....	597
stations.)		schools in United States.....	895
experiments, coordination of effort in....	7	schools, purposes and ideals.....	792
extension and experiment stations, rela-		statistics—	
tion.....	498	in Argentina.....	690
extension in Alberta.....	698	in British India.....	291
extension in high schools.....	293, 595	in England and Wales.....	393, 690
extension in Netherlands.....	95	in Finland.....	894, 895
extension in United States, origin and		in Galicia and Bukowina.....	93
development.....	896	in Germany.....	494
extension, school credit for.....	293	in Ireland.....	393, 494
implement sheds, construction.....	590	in Java and Madura.....	594
implements, data sheets.....	590	in Kentucky.....	290
implements in Argentina.....	590	in Missouri.....	689
implements, purchasing cooperatively...	290	in Netherlands.....	393
instruction—		in Portugal.....	690
home project work in.....	896	in Queensland.....	393
in Austria and Denmark.....	895	in Russia.....	594
in Canada.....	495, 690, 793	in São Paulo.....	291, 690
in Denmark.....	896	in Spain.....	791
in high schools.....	594, 691, 895	in Switzerland.....	393
in high schools of Michigan.....	692	in United States.....	594
in Ireland.....	596	in Uruguay.....	690
in Michigan.....	495	tenancy in Illinois.....	892
in Netherlands.....	95	tenancy in the South.....	893
in North Carolina.....	596	Agriculture—	
in Philippines.....	292	at American Association for the Advance-	
in secondary schools.....	691	ment of Science.....	2
in western Canada.....	698	Department of. (See United States De-	
papers on.....	198	partment of Agriculture.)	
(See also Agricultural education.)		elementary, textbook.....	692
insurance in New England, Mass.....	192	in Alaska, Alaska.....	791
investigation, examples of.....	306	in Argentina.....	689
investigations in Netherlands.....	95	in Australia.....	93, 791
investigations, physics in.....	106	in California.....	93
investigators, training.....	101	in Canada.....	791
journals, new.....	800	in Ceylon.....	393
laborers in Ireland.....	791	in Chosen.....	690
law in New York.....	688	in Denmark.....	791
laws in Massachusetts.....	898	in England.....	594
laws in North Dakota.....	493	in England and Wales.....	789
legislation, yearbook.....	393	in Germany.....	291
machinery as affected by European war..	86	in Hawaii.....	291
machinery, data sheets.....	590	in Imperial Valley, Cal.....	789
machinery in Argentina.....	590	in India.....	494
mechanics in Cambridge University.....	699	in Ireland.....	594
meteorology. (See Meteorology.)		in Japan.....	594, 690

Agriculture—Continued.	Page.	Alfalfa—Continued.	Page.
in Latin America.....	699	culture in New England.....	335
in New Zealand.....	690	culture under dry farming.....	529
in North Carolina.....	494	culture under dry farming, Utah.....	528
in Norway.....	896	cutworms affecting, Nev.....	53
in Philippines.....	93	diseases, notes.....	543
in Pinar del Rio, Cuba.....	791	ensiling with corn, Can.....	76
in Portuguese Angola.....	393	fertilizer experiments, Mass.....	121
in Scotland.....	291	fertilizer experiments, Ohio.....	829
in Spain.....	638	fertilizer experiments, Wis.....	626
in Sweden.....	690	for pigs.....	370
relation of eugenics to.....	92	for pigs, U.S.D.A.....	133, 170, 171, 767
relation to climate and soils.....	417	for sheep, U.S.D.A.....	169
relation to manufacturing in New Eng- land.....	391	green manure for, U.S.D.A.....	133
relation to native vegetation in Peru.....	27	growth and nitrogen-fixing power on acid soils, Wis.....	514
school exercises in.....	596	growth as affected by alkali, Utah.....	118
science and practice in.....	2, 604	harvesting and shrinkage, U.S.D.A.....	132
textbook.....	394	harvesting at different stages, Kans.....	171
tropical, technical education in.....	896	hay, digestibility, N. Mex.....	470
<i>Agrius sinuatus</i> . (See Pear-tree borer, sin- uate.)		hay for work horses, Kans.....	171
<i>Agromyza destructor</i> n.sp., description.....	658	hay v. oat straw for steers, Can.....	269
Agronomy—		inoculation.....	197
problems in.....	197	inoculation experiments.....	335
terminology in.....	327	insects affecting.....	152
<i>Agrotis ypsilon</i> . (See Cutworm, black.)		irrigation experiments.....	886
Air—		leaf spot, notes, Mich.....	735
conditioning apparatus, description, Kans.....	152	leaf spot, studies.....	450
upper, of Australia, U.S.D.A.....	19	meal, analyses, Can.....	65
(See also Atmosphere.)		meal, analyses, Ind.....	268
Akron (Colo.) field station, description, U.S.D.A.....	33	meal, analyses, Ky.....	258
Alabama College—		meal, analyses, Mass.....	667
and Station, notes.....	196, 397	meal, analyses, Mich.....	765
Station, report.....	693	meal, analyses, N.J.....	167
Alanin in yeast protein.....	501	meal, analyses, Tex.....	765
Alaska Stations, report.....	497	root development as affected by clipping seed, inspection in Maryland, Md.....	832 442
Albumin—		selection experiments, Mich.....	735
egg, in baking powders.....	561	sickness, notes.....	541
labile, relation to living protoplasm.....	225	Spanish, culture and identification.....	36
Alcohol—		transpiration in, U.S.D.A.....	226
amyl, use in milk fat tests.....	507	varieties, Alaska.....	435, 436
determination in fermentation mixtures.....	50	varieties, Nev.....	36
effect on psychological processes.....	763	varieties, U.S.D.A.....	133
effect on solution of casein by sodium hydroxid.....	108	varieties, Wis.....	828
substituting for sucrose in fixed diet.....	364	white spot, notes, Conn. State.....	47
Alcoholic specimens, keeping.....	252	wilt disease, description, Can.....	47
Aldehydes in soils, harmful effect.....	424	winterkilling, Wis.....	828
Ale, composition, U.S.D.A.....	864	yellow-flowered, studies, U.S.D.A.....	334
<i>Aleurocanthus woglumi</i> , remedies.....	457	yellow leaf blotch disease.....	248
Aleyrodidæ—		Alga, destruction in drinking water.....	183
classification.....	755	Algaroba tree, culture experiments, P.R.....	340
of British Guiana.....	252	Algocyan, notes.....	202
Alfalfa—		Alkali—	
composition as affected by maturity and curing methods.....	201	and salt industry, treatise.....	428
crown gall, notes.....	747	bush ash, analyses.....	429
crown wart, studies.....	543	destructive action on vitamins.....	465
culture experiments.....	332, 735	effect on creatin elimination.....	161
culture experiments, Can.....	32	production in soils by denitrification....	321
culture experiments, U.S.D.A.....	131, 132	salts, effect on crop growth, Utah.....	118
culture in eastern United States, U.S.D.A.....	95	soils or lands. (See Soils, alkali.)	
culture in Iowa.....	635	Alkalimetry, indicator for.....	13
		Alligator pears. (See Avocados.)	
		Allodus, North American species.....	542
		<i>Allorhiza obtusa</i> , notes, Me.....	460
		Allspice, germicidal effect, Wis.....	864

	Page.		Page.
Almond—		Amsterdam Colonial Institute, notes.....	699
Glœosporium disease, notes.....	453	<i>Amygdalus nana</i> , drought resistance.....	734
leaf and twig curl.....	647	Amylase in ripening horse beans.....	526
Almonds—		Amylases—	
crown gall resistance in.....	352	action on soluble starch.....	315
pollination, Cal.....	139	substrate for testing.....	316
<i>Alternaria</i> sp.—		<i>Anagrus bartheli</i> n. sp., description.....	857
on sweet cherries.....	452	Analytical methods, editing.....	299
temperature relations, U.S.D.A.....	649	<i>Anametis granulata</i> , notes, N.Y.State.....	549
Aluminum—		<i>Anaphoidea luna</i> , studies.....	759
dairy utensils, tests.....	571	Anaphylaxis—	
determination.....	203	produced by sensitization through	
phosphate, fertilizing value, Wis.....	626	vagina.....	277
Alunite as a source of potash, U.S.D.A.....	17	studies.....	677
<i>Amblyteles putus</i> , notes, Mass.....	54	<i>Anasa andresii</i> , notes.....	55
Ambrosia beetles injurious to sal.....	360	<i>Anelysis rubeculana</i> , studies, U.S.D.A.....	254
American—		Anemia—	
Association for the Advancement of Ag-		equine, studies, Nev.....	79
ricultural Teaching.....	198	infectious, in horses.....	581
Association for the Advancement of Sci-		infectious, in New York.....	676
ence.....	1	Anesthesia, effect on hemolytic reaction....	878
Association of Farmers' Institute		Anesthetics, effect on permeability of plant	
Workers.....	194	tissues.....	29
Association of Medical Milk Commissions.	572	(See also Ether and Chloroform.)	
Farm Management Association.....	297	Animal—	
Road Builders' Association.....	90	breeding, manual.....	667
Society of Agricultural Engineers.....	397	diseases, control in United States.....	675
Society of Agronomy.....	197	diseases, diagnosis.....	575
Wood Preservers' Association.....	45	diseases, dissemination in South Africa..	678
<i>Aeromyzobia aphelinoides</i> n.g. and n. sp., de-		diseases, immunization.....	575
scription.....	556	diseases in Assam.....	879
<i>Ametastegia glabrata</i> as an apple pest,		diseases in Bihar and Orissa.....	879
U.S.D.A.....	461	diseases in Burma.....	879
Amino acids—		diseases in Canada.....	179, 275
and carbohydrates, reaction between....	412	diseases in Egypt.....	180, 777
effect on cobra venom hemolysis.....	276	diseases in England.....	275
in stomach and intestines on vegetable		diseases in Great Britain.....	378, 676
diet.....	664	diseases in Iowa.....	777
Ammonia—		diseases in Maryland.....	777
absorption by soils.....	219, 425, 816	diseases in Massachusetts.....	79
assimilation by plants.....	631, 632	diseases in United Provinces.....	676
determination.....	413	diseases, protozoan, notes.....	880
determination in urine.....	316	diseases, transmission by insects.....	479
